Information technology security threats are most often defined as being "those circumstances or events that constitute potential danger to the normal state of a communication and information system, in which the confidentiality, integrity and availability of information, resources and services are ensured" (Ministry of Communications and Information Society, 2011).

Organizations have to expand and deepen their current information security risk frameworks to address these key threats (Andress, 2003; Hong, Kim, & Cho, 2010; Mittelman, 2011). This process implies a more profound understanding of the risks associated with each threat, and a better capacity of tailoring the security framework to align with the organization's identified risks, regulatory requirements and perhaps most important – the increasing dependencies on information technology (Willems, 2011; Stepchenko & Voronova, 2015; Malatras, Geneiatakis, & Vakalis, 2016; Lin, Lin, & Pei, 2017). In addition, as we pointed out previously, management vision must change radically, from a passive or reactive management style to a proactive style, ready at any moment to face the challenges of achieving the objectives of the organization (Tiago, Manoj, & Espadanal, 2014; Agrawal & Tapaswi, 2017).

Contrariwise, the allocation of material resources, human and too big for the risk management process can lead to non-completion of projects or even not starting them. This is where the organization's approach is to stop the progression of the project until the risk management process.

Another important aspect to note is that of a special form of risk, namely the risk of managerial behavior in the face of organizational changes: managers hoped that the change will solve the fundamental problems of the organization; there is insufficient time for planning the implementation of change;

sometimes ignore the importance of training and staff development in the context of change that will take place; change is successful only if the organization's staff change their attitude to adapt to new conditions created by the change; implementing a system with increased security personnel responsibilities (Yang, Wu, & Wang, 2014).

The key to harmonizing relations between manager and staff of the organization is to understand the thinking of the latter. Through this process of understanding and by developing and implementing coherent training policies, the management can complete the performances of the implemented security system (Kesan & Hayes, 2012; Arukonda & Sinha, 2015; Gandino, Celozzi, & Rebaudengo, 2017). Otherwise, it can be concluded that substantial resources have been allocated for the implementation of the security measures system and its efficiency cannot be determined.

Risk analysis is the first stage of risk management and is a crucial component of this process. It provides an assessment of the potential exposure to environmental threat, and the basis for the definition of the events -acceptable and unacceptable from the point of view of organization. The result of this process helps to identify appropriate measures to reduce or eliminate the identified risks. To determine the probability of an undesirable event, threats to the organization should be analyzed in conjunction with the potential vulnerabilities and security measures already implemented (Karim, 2007).

At the same time, Oncioiu (2016) agree that no matter the field of interest, no matter the dimension or type, almost every organization nowadays deals with a lot of sensitive information handled in computer systems: personal data related to their own personnel or customers, commercial data and analysis, industrial patents and so on. Regardless the complexity of the communication and information systems, starting from simple architectures of stand-alone systems to local area networks or wide area networks, managers should be aware of the need to implement proper information security policies in order to build trust in its network services, for both their own personnel and for partners (Smith, 2005; Winkler, 2010; Krombholz, Hobel, Huber, & Weippl, 2015; Broadbent & Schaffner, 2016; Kurosawa, Ohta, & Kakuta, 2017).

But then, communication and information systems are more and more widely used on a large scale in the process of command and control of national critical infrastructures, such as energetic, transportation, telecommunications and health (Wang & Hu, 2014). Each day the society becomes more and more dependent on these information infrastructures that become a backbone of vital information flow (Hiller & Russel, 2013; Gaidelys & Valodkiene, 2011; Okamoto & Takashima, 2015; Fischbacher-Smith, 2016).

In this context, it is of major interest that managers be aware of the importance of establishing correct information security policies, commensurate with the sensitivity of the data their companies process, transmit or store in electronic format (Liaudanskienel, Ustinovicius, & Bogdanovicius, 2009; Collins & McCombie, 2012; Singer & Friedman, 2014; Friedberg, McLaughlin, Smith, Lavery, & Sezer, 2016).

In the opinion of other specialists, such as Landoll (2010) risk analysis is defined as an objective analysis of the effectiveness of the security measures in place to protect the interests of the organization and a determination of the likelihood of prejudice to those interests. More specifically, risk analysis is defined by Peltier (2010) as a process of calculating risk. Algorithms for calculating the risk calculated risk as a function of the organization's assets, threats and vulnerabilities.

RESEARCH METHODOLOGY

In order to get an image of the Romanian organizations' attitude towards security of information they process, transmit or store using communication and information systems, the authors performed a detailed

survey using questionnaires. The research activity's aim was to study the information security policies and mechanisms implemented within the Romanian organizations and had the following objectives: determine the level of awareness regarding the necessity of information security policies and mechanisms; determine if the managerial decision-making is performed on the basis of information security risk management results; determine the dynamics of the security threats towards information handled in communication and information systems.

The survey was performed during the second trimester of 2017. The questionnaires were forwarded to 220 security practitioners, receiving back a number of 158 responses (72%). We choose to receive anonymous responses, in order to enhance the probability of getting more realistic responses. Responses were collected using questionnaires processed using the Scientific Package for Social Sciences (SPSS) 17.0 and the making of the database structure was achieved by defining variables in Variable View. It is also important to note that all completed questionnaires were checked in terms of background completeness and usefulness of data and using the statistical program previously mentioned, data analysis was materialized through frequency tables and histograms for each item, and the centralization of all items.

In addition to the related tables and histograms, data analysis led to an emphasis of statistical indicators for this study, namely: the mean, median, mode, standard deviation/standard error, variance, amplitude of variance, minimum, maximum, the sum of all observations, the coefficient of asymmetry Skewness, the coefficient of vaulting Kurtosis and the calculation of quartiles.

SOLUTIONS AND RECOMMENDATIONS

Following the results of this research, Table 1 presents the results of several regression analyses. Organizational performance was supported, as information security awareness programs was positively associated with organizational performance ($\beta = .25$, $p < .001$). The benefits of information security are weighed against their total cost was also supported as organizational performance was positively related to financial results ($\beta = .36$, $p < .001$). Finally, implementing security measures was supported as the partial regression coefficient of organizational performance reached statistically significant ($\beta = .27$, $p < .001$) after controlling the effect of information security awareness programs.

Table 1. The Linear Regression of information security awareness programs and organizational performance

	Organizational Performance	Benefits of information security are weighed against their total cost	Implementing security measures
	β (t value)	β (t value)	β (t value)
Information security awareness programs	0.25 (4.65***)	0.36 (6.15***)	0.27 (3.98***)
Organizational Performance	-	-	0.168 (2.72***)
ΔR^2	0.17	0.22	0.07
ΔF value	44.95***	73.11***	15.32***
Overall R^2	0.17	0.24	0.22
Overall F value	43.96***	76.10***	51.84***

Note: *** $p < .001$, β = standardized regression coefficient, t value = test statistics of β

As previously shown, the evaluation of the results of an awareness program is important from at least two perspectives. First is the program's objective itself. If the program does not achieve its objective of enlarging the user's knowledge regarding the threats and vulnerabilities that may affect information handled within their organization, the mission of the organization may be at risk. Second perspective is that the awareness program must be developed and improved in accordance with the organization's needs and target audience. A lack of effectiveness should trigger an improvement process of the program. Feed-back on the program should always be required from both the participants to the program and the managers that have responsibilities over the information systems within the organization.

In this context, experts recommend all users from the business, and the individual, pay increased attention in the next period the following:

- Dangers of Web 2.0. The popularity of Web 2.0 applications will continue to generate problems in the next period. Hackers will use attack techniques portions of code and will continue to use Internet browsers and other software (such as Flash or media players) as vectors of spread of infection. Launch Google Chrome, Internet Explorer 8 and the advent of the new software type web platform (such as Microsoft Silverlight and Adobe Integrated Runtime) are potential launch pad for new attacks.
- Vulnerabilities in websites and web applications. Companies operating in the online environment will have to pay extra attention this year web applications and web sites that we develop. Criminals will try to exploit any vulnerability in web applications present to take possession of information about users (name, accounts, passwords, email addresses) for later use in activities phishing or spam. Periodic auditing of websites and web applications will be essential for companies online.
- Policies multi- level security. The next period will be marked by a number of economic challenges that companies will have to face in a most professional and least cost. Securing IT infrastructure on all levels will be crucial to the smooth running of any company in the period ahead. Operational stability, secured by a security policy very well put together, it will be a competitive advantage for most organizations.

Nevertheless trust can be based both on objective and subjective factors. The objective elements underlying confidence building can be, for example, results of the IT & C products used or the security measures that convey information systems sensitive. Level of experience, stability is subjective elements which complete and sometimes even replace, the objective elements on which trust entity. In general, trust is associated with certain circumstances, such as the total amount transacted, sensitivity or criticality of information, the potential loss of property or life, etc. Confidence in an entity is not transitive and gaining general experience and measurements.

Between the concepts of risk, organizational culture and trust there is a direct relationship. Changing an organization's operational needs as determined for example by changing mission requirements and exchange information with other entities may involve changing risk tolerance level, above the level set by the management of the organization. These measures lead to building confidence in the organization long term.

FUTURE RESEARCH DIRECTIONS

As for the next period, it is expected that the main threats confronting the communication and information systems will be targeted to system hardware and software architecture, taking the form of attacks of the peer to peer architectures, attacks directed at application level or at operating system level (Choi et al., 2014; Khan, Gani, Wahab, Shiraz, & Ahmad, 2016). The competition between different networks of online criminals will intensify these gains as wanting to attract large cyber-attacks, both through viruses and worms, and especially by botnet structures. The most important networks of criminals currently come from Eastern Europe, including Russia and China. As a result, security specialists warn that these regions will be those that will generate a large number of exploits next years.

Withal, the interaction between trust in organization and organizational culture can also be observed when there is overlapping responsibility or uncovered areas between various parts of an organization may impact on the ability to undertake operative.

Demonstrating that the organization has structures and procedures to ensure effective protection of information that circulates determines both the organization's external partners (suppliers, customers, entities whose business depends on the organization in question) and to staff the faith that the organization operates in a consistent manner based on clear rules and procedures, which leaves no room for chaos and bias.

CONCLUSION

Communication and information security incidents record a significant growth during the last years, both in number and complexity (Yar, 2006). The main motivations of large scales attacks are financial profit or political supremacy. The complex cyber-attacks in 2007 on Estonia, Lithuania and Georgia are the most widely covered examples of a general trend. The huge number of viruses, worms and other forms of malware, the expansion of botnets and the continuous rise of spam confirm the severity of the problem (Ministry of Defense Estonia, 2008).

The goal of information security is to be able not just to put in place measures to detect and mitigate attacks but also to preemptively predict attacks, deter attackers from attacking and thus defend the systems from attack in the first place. A superficial evaluation of the information security assembly, including security awareness, leads to the lack of feed-back necessary for the decision-making process with regard to the necessity of implementing adequate corrective measures for improving the information security management. In this context, information security policies are adopted on empirical criteria, without being based on a critical assessment of the internal and external factors characteristic to the organization.

According with the results of this research, in order to consolidate and improve the information security posture, efforts should be based on a series of few principles that we consider to be essential bricks towards a building trust and credibility: coordination, meaning that all policies approved and actions taken to be circumscribed to a unitary concept, according to convergent plans of action towards attaining information security, according to responsibilities and competencies of each organizational department within the organization; a team-oriented approach is vital in fighting against information security threats; cooperation, meaning that all entities having responsibilities (either public institutions or private companies or non-governmental organizations) should collaborate at international, national and organizational level, in order to ensure an adequate response to information technology threats and to possible successful information security attacks; efficiency, meaning that all resources, either

financial, human, material, have to be correctly allocated and managed in order to address the primary needs and priorities; prioritization, meaning that the efforts have to be focused on the protection of those communication and information systems supporting critical functions of the society and, respectively, of the organization; dissemination, meaning that a proper transfer and sharing of information, expertise and best practices have to be ensured among persons with responsibilities in the field of protecting communication and information systems handling sensitive information or supporting critical functions.

Romania made positive steps in enforcing an information security management framework and it is continuously striving to improve it, in cooperation with its European and Euro-Atlantic partners. Still, there are steps to be made in order to improve the attitude of Romanian organizations towards security of information handled in communication and information systems. That is why government organizations are developing information security awareness programs targeting both public and private organization security practitioners. The primary objective of these programs is to raise the information security awareness of this category of personnel, with a view to improve the general public understanding and attitude towards information security.

As an overall conclusion following the processing of the data gathered through this survey, we appreciate that at the level of Romanian organizations, both public and private, there is a relative high level of awareness regarding the necessity to implement policies and mechanisms to ensure the security of information handled in communication and information systems. For all that, almost half of these policies and mechanisms are not developed on an assessment of the organization's operational environment, to include information security risk assessment to organization's mission and interests.

More than that, on one hand, managers are aware of the necessity of establishing measures for the protection of the information they handle in communication and information systems while, on the other hand, the decision making regarding the selection and implementation of the most adequate measures to protect their information is not founded on objective considerations, specific to the activity and interests of their own organization. These measures are more like "implanted" in their own organizational environment.

Having in mind the conclusions outlined before, we consider that an improvement of attitude towards information security would be of benefit for the decision making process within the Romanian organizations. Awareness rising programs should be developed in order to promote the practice of building decisions upon objective assessments of the organization's realities. This kind of practices ensures a better balance between costs and benefices and a better allocation of resources. But then, a higher level of awareness for the personnel may allow the replacement of certain technical security measures with procedural measures, thus reducing the costs allocated to hardware, software, maintenance etc.

KEY TERMS AND DEFINITIONS

Integrity: The prohibition amendment - by deleting or adding - or the unauthorized destruction of information; integrity refers to confidence in the data and resources of a system by which to manage information.

Prevention: Implementation of mechanisms that users not be able to counteract and are implemented correctly, unaltered, so the attacker cannot alter them.

Risk Management: The implementation and updating of methods and tools to minimize risks associated with the information system of an organization, such as the Information Security policies, procedures and practices associated formalized and adopted other means in order to bring these risks to acceptable levels.

Threats: The possibility of accidental or deliberate compromise of information security, the loss of confidentiality, integrity or availability or impaired functions that provide authenticity and non-repudiation of information.

INTRODUCTION

Nearly forty years ago, futurist Alvin Toffler published *The Third Wave* (Toffler, 1981). In this book, Toffler describes the evolution of human society as the concept of waves. Specifically, *the first wave* is the transition of hunter-gatherer society to an agricultural society, which occurred around 10,000 BC; *the second wave* is the transition of agricultural society to industrial society, which started 200 years ago; and *the third wave* is the transition of post-industry society to information age, which is happening right now.

Forty years ago, not too many people were using computers. The fastest computer in the world at that time is probably slower than the smartphone in your hand now. Forty years later, when we look around, we are amazed by the accurate predictions made by Toffler and impressed by how much we are dependent on information technology.

Information technology is transforming our society in every aspect, such as education, healthcare, entertainment, finance, transportation, engineering, and more. Information technology revolution can provide us new tools and new experiences, which are especially welcomed by new generations. However, besides the positive impacts, information technology revolution also brings challenges for traditional businesses, which are unfortunately classified as sunset industry. This impact could be massive. In the past twenty years, we have witnessed the rise and fall of various business models due to the revolution of information technology.

Undoubtedly, we are living in a critical era filled with ideas, opportunities, and conflicts, especially in the business field. Information technology-enabled business (e-business) is changing our lives, our society, and our world (Markoff, 2005). Generally speaking, e-business (electronic business) is the conduct of business processes on the Internet. These new business models include e-commerce, mobile payment, marketplace lending, social networking, digital advertisement, mobile-enabled transportation, virtual games, virtual entertainment, and distance education. Some of these e-business models are mature and well known, such as e-commerce. Others are relative new. This paper describes some of the emerging e-business models that are transforming our society, including marketplace lending, mobile-enabled transportation, peer-to-peer rental, and personalized marketing. The objective of this paper is to help readers understand the dynamic features of business activities, especially when they are under the influence of information technology, so that people can better adapt to the changing world.

MARKETPLACE LENDING

Background

Lending is one of the oldest financial activities, in which money is borrowed by one party from another party. The borrower is obligated to pay back the money with accrued interest. A traditional peer-to-peer lending occurred between one borrower and one lender. This kind of model clearly put the lender in a risky position, because if the borrower cannot pay back the loan, the lender's business will not be able to sustain.

Banks are considered a better lending solution, because the money of individual investors is consolidated by the bank and then lent to borrowers. The risk of loan default of an individual borrower is averaged down to many lenders. Although this lending model takes a less risk, it has the disadvantage of low return rate (interest rate) on investment, because part of the lending profit goes to banks.

Banking business began about 2000 BC in Assyria and Babylonia. In the following 4000 years, bank-based lending business played significant roles in the evolution of human business activities and human society (Green, 1989). Especially in the past two centuries, financial institutions (like banks), were among the most influential factors to shape the modern world. The highest buildings in downtowns of most cities belong to banks; their branches are accessible anywhere in the world; their advertisements appear in major media all the time.

As the evolution of information technology has redefined many business models, the lending business is no exception. A new Internet-based peer-to-peer lending emerged. To distinguish this lending business from the traditional peer-to-peer lending, it is also referred as marketplace lending.

The idea of marketplace lending is that both the borrowers and the lenders come to an Internet-based platform (marketplace), where they are matched with the support of complex computer algorithms. In many platforms, the lenders have a choice to pick the category of borrowers, and the risk of loan default is known to the lender. Because the lending platform is Internet based and it can attract users everywhere, the business is easy to scale up. In addition, the lending process is supposed to be monitored by and conducted through computer programs, the business cost could be reduced. Therefore, it is a win-win solution for both the lender and the borrower: the lender is expected to receive a higher return rate than the bank interest and the borrower is expected to pay a lower interest rate than the regular bank rate (Moldow, 2014).

Status Quo

Lending Club is the leader of marketplace lending in the US. It was launched in 2007 (Mach et al., 2014). On *Lending Club*'s online platform, borrowers need to provide personal, financial, and loan information so that the computer program can decide whether to grant the loan. If the loan is granted, the interest rate will be determined by the borrowers' credit history and payback ability. Meanwhile, Individual lenders could invest on these loans through the *Lending Club* platform. Their investments could be subdivided into small chunks for different borrowers in order to average down the risk of loan default of individual borrowers. *Lending Club* profits from charging service fees to the lenders.

Because the loan demands grow faster than individual investment, *Lending Club* also bundle the loans and sell them to institutional investors, like banks. There are two important features of *Lending Club* business. First, the loan is not secured and it is not guaranteed that the lenders could always get

their investment back. Second, *Lending Club* does not directly invest in any loans, which prevent it from taking any risks of loan defaults.

Yirendai is a leading online lending marketplace in China. Its operation is supported by its parent company CreditEase, a financial institution that provides credit rating services. *Yirendai*'s borrowers and lenders could reach a deal through its online or mobile platform. The advantage of *Yirendai* over other competitors in China is that many high credited borrowers are referred from CreditEase's offline business network.

Similar to *Lending Club*, *Yirendai* generates revenues from service fees. Different from *Lending Club*, in *Yirendai*'s platform, borrowers' information, such as income, education, employment, loan amount, and loan purpose is openly available to investors. The investors can choose which loan to invest and how much to invest. In addition, *Yirendai* does not directly lend its own capital to borrowers. Instead, *Yirendai* uses its own capital as a reserve fund to pay out the default loans if needed. This kind of business practice can assure the confidence of the investors (Huang et al., 2016).

Lending Clubs' loan is basically unsecured; the investors take the default risk by themselves. *Yirendai*'s loan could be misunderstood as secured because of the reserve fund. However, during the time when the whole society is facing financial hardship and default rate is too high, it will not be possible for *Yirendai* to pay out all the default loans. Because *Lending Club* takes no risks of default loans, it might be easy for it to live through a financial crisis, while *Yirendai* could go bankrupt in a national or global economic turmoil.

Other marketplace lending companies in the US include *Prosper*, *SoFi*, *LendingRobot*, and *Stilt*. They operate on similar business models as *Lending Club*. However, their business grows fast. Especially, *Prosper*, which is America's first peer-to-peer lending marketplace, now becomes a major competitor of *Lending Club*. In 2017, *Prosper* had \$2.9 billion loan originations, while *Lending Club* had about \$9.0 billion loan originations.

Globally, marketplace lending is also growing. Representative platforms include *Zopa*, *Funding Circle*, and *RateSetter* in the UK, *Lendix* in France, *Auxmoney* in Germany, *Mintos* in Latvia, *Bondora* in Estonia, *Funding Societies* in Singapore, *WeLab* in HongKong, and *Maneo* in Japan.

Impact

In the United States, marketplace lending is growing, but with many conflicts. *Lending Club*, *Prosper*, and other platforms all have different issues, like management and marketing. On the other side, feeling the competitions from marketplace lending, some traditional financial institutions begin to shift their business models to peer-to-peer lending. For example, at the end of 2016, Goldman Sachs launched *Marcus*, a peer-to-peer online lending platform. This movement signaled the beginning of the transitions of the traditional banking industry.

Unlike in the United States, where marketplace lending is closely regulated by the government, China's marketplace lending is growing with less regulations, at least until now. A lot of fake marketplace lending platforms operated like Ponzi-like scheme were out of business in the past several years. This caused millions of investors losing their money. Therefore, the Chinese government is working to establish regulations for marketplace lending. Currently there are still hundreds of marketplace lending platforms in China. It is expected that most of them will lose their operating licenses after the regulations take effect. The ones that could survive will grow stronger and bigger.

MOBILE-ENABLED TRANSPORTATION

Background

Taxi service has been around for 300 years. These services appeared first in Paris and London, and later in New York City. After gas-powered taxicabs were introduced in the 1890s, taxi service gradually became popular in big cities worldwide. In contrast, car-sharing business began in 1940s in Zurich Switzerland. The first official car sharing business in the United States appeared in Portland.

Mobile-enabled transportation applications include mobile taxi service and mobile car-sharing service. Traditionally, a taxi service is established through a moderator in the taxi company. A service needs to be reserved in advance and usually not many choices are available for the passenger. Similarly, traditional car sharing is rare; it might only happen between friends and relatives. However, with the advancement of mobile computing technologies, new transportation business models appear (Zhang et al., 2017).

Mobile-enabled taxi service is a platform that connects taxi drivers and passengers. The locations of both the drivers and the passengers are visible, allowing them to contact each other. In addition, the passenger's detailed request can be sent to the driver in real time, allowing them to reach an agreement in a short period of time. Generally speaking, the service platform does not own any taxi. Instead, contracted taxi drivers should pay the service fees to the platform.

Mobile-enabled car-sharing service is a platform that allows car owners and car renters to communicate and negotiate. Again, the platform does not own any cars. It is mainly used to connect car owners and car renters and facilitate them reaching a deal. Afterwards, a service fee could be collected.

Status Quo

The most important player in this business field is *Uber*, which is founded in 2009 and headquartered in San Francisco of the US. It operates its business in over 6 hundred cities worldwide. Contracted *Uber* drivers use their own cars to provide taxi services. The supporting platform is a mobile app. By the end of 2017, *Uber* has about 7 million drivers and over 50 million riders worldwide. In the US, *Uber* has about 74% ride-sharing market share.

In China, the business leader is *Didi Chuxing*, which is founded in 2012 and headquartered in Beijing. It acquired *Uber*'s China business in 2016 and became the market dominator. *Didi Chuxing* is invested by China's internet giants Tencent, Alibaba, and Baidu. *Didi Chuxing* provides mobile services for taxi, express carpool, social ridesharing, designated driving, car rental, etc. Because of the large population base, *Didi Chuxing* has about 450 million riders. *Didi Chuxing* has about 87% market share in China. However, *Didi Chuxing* is behind *Uber* in international expansion.

Globally speaking, there are several other competitive mobile-enabled transportation service platforms. They include *Careem* of the Middle East, *Grab* of the Southeast Asia, *Ola* of India, *Yandex.Taxi* of Russia, *Taxify* of Europe and Africa, *Easy Taxi* of the South and Central America, and *Gett* of Israel.

Impact

Apparently, the mobile-enabled transportation apps improve the efficiencies of taxi industry and car-sharing industry. However, the benefits could be tilted to those who adapts quickly to the new business models. For traditional drivers and car owners, who are reluctant to switch to these new platforms, they could see their loss of business and decrease of income. In the US, China, and some other countries, we

have seen mobile-enabled taxi apps and car-sharing apps were banned in some cities before agreements were reached between traditional business unions and the new service providers.

For consumers, the mobile-enabled transportations are beneficial to and favored by new generations. However, for old generations who do not know how to use these services or who do not own a smart-phone, they might have found out that now days, it is more difficult to book a taxi or rent a car because of reduced traditional service providers. For them, technology evolution is detrimental to their lives.

PEER-TO-PEER RENTAL

Background

Hotel business has the same history as human civilization (Levy-Bonvin, 2003). It appeared as early as 2000 years ago. Clearly, booking was not needed in this business until telephone is invented 100 years ago. After the introduction of the Internet into this business, reservations can be made through the website of the hotel or a third party. Hotel business has been the major accommodation and lodging provider for tourists and short-term visitors, until recently it begins to feel the competitions from online peer-to-peer rental services.

Peer-to-peer rental refers to the process of one person renting an owned good, service, or property to another person. It is another example of sharing-economy business model innovated through the Internet. The most popular form of peer-to-peer rental is property rental (Fraiberger & Sundararajan, 2015).

The foundations behind peer-to-peer rental are twofold. First, if someone has a property and they rarely use it, it makes sense to rent the property out to make some profit to cover the cost of utility, maintenance, and tax. On the other side, if someone has a unique request for a short-term vacation home, regular apartments and hotels might not be able to satisfy this requirement. Instead, peer-to-peer rental could be the best solution. Second, with the support of the Internet, property owners and property renters could be connected together in the virtual space even they might live far away. A business contract could then be established and executed through a third-party service.

The online service website that hosts owner's property information and allows renters to search and browse the property and contact the owner is the emerging peer-to-peer rental business. Again, this is an Internet-based new business model.

Status Quo

Airbnb is a leading marketplace of peer-to-peer rental in the world (Zervas et al., 2014). It is founded in 2008 and headquartered in San Francisco. *Airbnb* hosts individual's rental information for vacation homes, apartment rooms, homestays, hostels, and hotels. Like other forms of online marketplace, *Airbnb* does not own any property. Instead, it is a broker between the owner and the renter and receives service fees from them for every booking. In January 2018, the company had over 3 million lodging listings in 65 thousand cities of 191 countries. In the third quarter of 2017, *Airbnb*'s revenue reaches US \$1 billion, which represents a 50 percent year-to-year growth. In the entire hotel industry, *Airbnb* has about 10% market share in some regions, such as the Western Europe. This number is impressive, because worldwide, *Airbnb* is competing with over 180 thousand hotels.

Besides *Airbnb*, other peer-to-peer rental marketplaces include *VRBO*, *Flipkey*, *RentalsCombined*, *Wimdu*, and *Go With Oh*. Some of them are operating their business globally; some of them focus on a specific area. For example, *Wimdu* and *Go With Oh* mainly list properties in Europe.

Impact

One apparent benefit of peer-to-peer rental is to help customers make efficient usage of resources and reduce overall operating expenses. However, the traditional hotel business is feeling the disruptive effect (Guttentag, 2015). They have to lower their prices and provide better services in order to attract tourists or other short-term or long-term guests. This competing process eventually benefits the consumers.

On the other side, it is not surprising that traditional hotels are feeling the competitions from peer-to-peer rental business. For example, a campaign has been waged by the American Hotel and Lodging Association to lobby lawmakers passing tough regulations on peer-to-peer rental (Fingas, 2017). Like other e-business models, competition is only fair when similar standards are applied to both the traditional business and the new business.

In addition, research found that peer-to-peer rental could also promote social interactions. Business could be conducted between strangers never met. More close relation could be established between the owner and the renter, if they happen to live under the same roof.

PERSONALIZED MARKETING

Background

Personalized marketing is also called one-to-one marketing or individual marketing. It is a customized marketing technique targeted on a specific potential customer. It is another example of technology-supported and mainly Internet-based business model.

Traditionally, advertisement on newspaper, radio, TV, or billboard was designed to target a large group of people with little attention to their diverse needs. Accordingly, the traditional mass marketing is considered business inefficient, especially for unpopular products and services. This kind of marketing strategy has been used for nearly 200 years (Tedlow, 2014). With the evolution of information technology and the Internet, personalized marketing becomes both technically available and practically possible.

The idea behind personalized marketing is that potential customer data could be collected, including age, gender, education, location, and shopping habit. There are many ways that a customer's data could be collected, such as from credit card companies, emails, shopping websites, location visible apps, and so on. The data could then be analyzed with big-data techniques. Potential customers for a specific product or a specific service will be identified (Cheung et al., 2003). Relevant advertisement will be delivered to these customers' emails, appear on the banner of the websites they visit, or on the front page of the apps they use.

Status Quo

Currently, popular software tools and services in personalized marketing include *Adobe Audience Manager*, *Adobe Target*, Oracle's *BlueKai* and *Eloqua*, and *Sitecore*. These tools and services are described below.

- *Adobe Audience Manager* is a data management platform that helps build unique audience profiles, identify most valuable segments of a customer, and use them on different digital channels.
- *Adobe Target* is a customer-targeting tool, which can be used for making marketing offers and personalization, allowing marketers to analyze the efficiencies of different marketing techniques.
- *BlueKai* is Oracle's cloud-based platform that supports personalized online, offline, and mobile marketing. For example, *BlueKai* collects users' information on surfing the web and smartphone app usage to improve marketing efficiencies for their clients, which included Twitter and Facebook.
- *Eloqua* was founded in Toronto, Canada and is headquartered in London, UK. Its main product is a marketing automation system for businesses, especially for large enterprises. It was acquired by Oracle in 2012.
- *Sitecore* is a customer experience management platform that provides web content management and multichannel marketing automation services. It is headquartered in Copenhagen, Denmark.

To summarize, the major players in personalized marketing business are *Adobe Systems* and *Oracle Corporation*. Other players include *Microsoft* and *Sitecore*. These companies basically play two roles in this business: identify more interested target customers and disseminate the advertising information more efficiently.

Impact

For business, the most important impact of personalized marketing is that marketing activities become more efficient, due to on-purpose targeting and automated delivering. The personalized marketing cost could be increased compared with traditional mass marketing technique. However, this new strategy eventually lead to the most crucial benefit: an increase in revenue.

For customers, personalized marketing is, generally speaking, also welcomed. First, consumers now days have a vast variety of choices for products and services. Personalized marketing can save their time and reduce their frustrations in browsing and comparing these products and services. Second, new generations of customers are more willing to share their data with companies in exchange for personalized offers and discounts. This shopping attitude promotes the company to shift from traditional mass marketing to customized-marketing (Chen & Hsieh, 2012).

Like other e-business models, personalized marketing service also threatens traditional mass marketing business. Newspaper, television, billboard, advertising mail and other mass marketing business are losing customers and revenues. On the contrary, social media, social network, email, and other websites or apps that can be utilized as personalized marketing platforms are booming. One reason that Facebook can become the most valued social network in the world is due to its monetization strategy focusing on the implementation of personalized ad (Tran, 2017).

In spite of the benefits of personalized marketing, allowing service providers to access personal data also brings risks to customers. If data is misused, it could generate substantial effect. One example is Facebook's user data was misused by Cambridge Analytica in the 2016 US presidential election.

FUTURE TREND

As illustrated in the previous four representative emerging models, e-business is growing tremendously fast and has a magnificent effect on our economy and society. No one would say that offline traditional

business will disappear. That might not happen soon. However, e-business has more dimensions to grow. More new e-business models could emerge with the advancement of information technology. The potential of e-business is undefined yet.

One trend of e-business is that they are pro to grow internationally. Compared with traditional business, e-business has less distance barriers. However, conducting business internationally is always a complex task. It is affected by government policies, local cultures, religions, and geopolitics. Globalization of e-business is facing all forms of trade protectionism. Uber's failure in China and Ant Financial (China's mobile payment service provider)'s failure to acquire MoneyGram of the US are typical examples of global expansion difficulties facing e-businesses (Hook, 2016; Roumeliotis, 2018).

Another new trend in e-business is the usage of smartphones. In the past decade, we have witnessed that many business activities are moving to mobile devices. Mobile payment and mobile-enabled transportation are two representative applications. Other e-business activities, such as shopping and renting, are also moving from online platforms to mobile platforms. The adoption of mobile technologies is reshaping the business landscape.

As discussed in the four representative emerging e-business models, technology revolution and business transformation could result in workforce layoff, store closing, and unemployment increase. Therefore, responsible government officials and business leaders should work together to make these transitions smoothly. Regulations should be passed and cooperative practices should be promoted to reduce the disruptive effect of growing e-business.

A good e-business model should create jobs, not kill jobs. In addition, the reduced business cost and improved business service should be beneficial to the majority of the population. As we enjoy the benefits of e-business, we should also be aware of the damages, especially the damages to social stability (Seelos & Mair, 2005). When technology is utilized in business, the government and the responsible national and international influential personage should work together to make sure the new e-business is not counteract to social inclusion.

A social relation or social interaction is any relationship between two or more individuals in the society. In traditional business, the social relation is characterized by the direct interactions between the service provider and the consumer. In contrast, e-business might only provide a virtual interaction between them. Accordingly, e-business could also bring in negative impacts on the new generations. People are spending more and more time online and it is easy for them to forget the real world outside. E-business, together with other technology-enabled fields, such as social networking, virtual entertainment, and distance learning, are reshaping the social relations and social structures.

CONCLUSIONS

This paper described several Internet-based business models, their status and impacts on traditional business. Specifically, this paper discussed the effect of these new business models on society. Looking forward, with the advancement of information technology, we could expect the emergence of some new business models in the near future. Below lists some of them.

- Localized businesses. With the wide usage of smartphones, location data can be integrated into the apps, which can facilitate localized activities, such as dating, garage sale, gaming, sports, and entertainment.

- Crowd-funded projects. It might not be easy for a new project or a new initiative to get support locally or from a large venture capital. However, with information technology and social network, they might attract investors, big or small, around the world.
- Customized products and services. Information technology enables us to create customized products and services for customers. For example, a customized textbook with appropriate chapters could be created for a course of a school. Customized services could also be developed in restaurants, accommodations, and entertainment businesses.
- Driverless transportation. With the support of AI technology, driverless cars and lorries are being tested in the United States and some other countries. For example, it is expected that driverless trucks could be a regular presence on many roads within the next 10 years predicted by International Transport Forum in January 2018.

E-business not only changes the way we loan and lend, transport, rent, and advertise, but also changes social structures and social relations. It is the responsibility of the government to actively regulate these business activities so that the majority population can benefit from this digital revolution.

KEY TERMS AND DEFINITIONS

E-Business: A business that part of its activities are conducted online or on mobile apps.

Marketplace Lending: An individual to individual lending that is conducted through a third-party online service (marketplace).

Mobile-Enabled Transportation: Taxi service reservation or car-sharing deal that are conducted through a mobile app.

Peer-to-Peer Rental: An individual property rental conducted through a third-party online service.

Personalized Marketing: A marketing strategy that delivers selective advertisement to potential customers.

Digital Technologies in Wholesaling and Retailing

8

Felix Weber

University of Duisburg-Essen, Germany

INTRODUCTION

The ever increasing intra/inter-competition, increased costs and a lower differentiation margin, have led to intense competitive pressures within the domains of the wholesale and retail industries. At the same time, the increasing digitization, due to technological innovation, will radically change the economical and procedural fundamentals. In addition, from an entrepreneurial point of view, it must also be considered that the complexity of decision-relevant framework conditions has increased. Therefore, digitalization should be viewed as an essential driver for optimizing business processes (Brynjolfsson et al., 2018), as well as the basis for a new understanding of products and services. The permanently emerging new technologies, all labeled as having huge impact on any industry, increasing the complexity even further. Many technologies have great impact, but only on limited industries and use cases. Adopting these technologies too early will certainly lead to frustration; just as the adopting of a technology too late can have a lasting impact which may put one out of business. A clear structure and assessment of upcoming technologies and trends is provided by the “Gartner Hype Cycle” (Walker, 2017), however, it is missing the retail industry specifics. Currently many studies about the application of technologies in retail and wholesale exist but are only limited to single technologies and their potential. Lot of scientific work exists regarding the role of big data and analytics (Bradlow et al., 2017), artificial intelligence (Krüger et al., 2011) or single task areas like pricing or marketing (Abels et al., 2018; Yeoman et al., 2017). But none of this work gathers all available technologies for all possible use-cases within the domain of retailing and wholesaling. This chapter will further elaborate the underlying technological trends, empowering the transformation processes within the domain of wholesaling and retailing. Starting with: the major technologies, the impact of technological advancements and opportunities, and the risks and constraints which are connected with it, are scrutinized. The results are finally summarized following the structure of a framework of the generic processes of trade companies.

A detailed overview of future technological trends that are relevant for retailing and wholesaling are provided. The structure allows scientist and practitioners to evaluate the impact and the potential areas of use, existing use-cases, and the overall potential for their processes of interest.

BACKGROUND

Value-adding Core Processes of a Trade Company

In order to reasonably structure the analysis of the purpose and potential relevance for the trade industry, this article orientates the main processes of a trade company. This structure will help practitioners, as well as researchers, to quickly find the relevant technologies for their area of interest.

DOI: 10.4018/978-1-7998-3473-1.ch089

Trade comprises the activities of purchasing goods from manufacturers or suppliers; transporting, stocking, and combining the goods to form an assortment; and selling them to commercial (wholesaling) or non-commercial (retailing) customers without the goods being modified or processed. The “Handels-H” (or Retail-H) is a reference model for modeling business information systems in trade (Becker & Schütte, 2004). As a framework, it structures all of the main processes of a retailing or wholesaling company and offers both; the process view and the data view of the functional areas within a retailing company. In the following the terms retail and wholesaling are used as synonyms as the core processes and also the implication of technologies on both are quite similar as just the counterpart of the transaction (natural vs. legal person) differ.

The “H”-part of the framework lists the value-adding core processes of a retail company. The functional area of procurement, which is usually directed to the vendor, is located on the left-hand side of Retail-H, with the main processes of: Purchasing, Materials Planning, Goods Receipt, Invoice Verification and Accounts Payable. The main processes: Marketing, Sales, Goods Issue, Invoicing and Accounts Receivable Accounting, are located on the right-hand side of Retail-H, as the processes to be assigned to the functional area of sales. The linking and merchandise management bridging element, between the functional areas of procurement and sales, is the warehouse process. Thus, the warehouse is an essential part of the logistics process, from: receipt of goods, warehouse and issuing goods.

The management processes of a retail company, after structuring the Retail-H reference model, are reflected in the roof section. The decision makers of the retail company use the processes of: controlling business intelligence and corporate planning, in order to prepare the data from the operational systems to serve as a basis for decision making and planning.

The business administration tasks, and thus, the support processes of the reference model, are visualized as the H and the roof supporting base. The indispensable main processes of: general and asset accounting, cost accounting and human resources management, support the core and management processes of Retail-H, without offering direct customer benefit.

From Technologies to Digital Technologies

On the one hand, “digitization” is the transfer of previous, non-digital data, for example, in the case of music. On the other hand, digitization expresses the process of reinventing or adapting business models, products and processes, through the possibilities of (information) technology.

The concept of “technology” is well proposed by Abele (2006), amongst others, according to which technology is composed of skills, knowledge and resources for solving technical problems and for resources (facilities or equipment) which serve to put scientific findings into practice.

To define “digital technology”, we elaborate this definition further, as, “digital technology is composed of skills, knowledge and resources related to the domains of information and computer engineering, which serve to put scientific findings into practice”.

The never-ending stream of new and evolving technologies, is catalyzed by different frameworks. These frameworks are mainly proposed by research companies trying to offer guidance to their customers. The “Hype Cycle” by Gartner, is one of the most popular and well-known examples. It is a derivation of the technology life-cycle approach by Krubasik (1982), which describes the generic evolution of new technology and its usage during a fictional timeline. The term “hype cycle” was coined by Gartner Consultants (Fenn, 1995), and is used today to evaluate the introduction of new technologies.

This is represented in a diagram (see Figure 2): on the Y-axis, the attention (expectations) for the new technology is plotted; on the X-axis, represents the time since announcement. The curve rises explosively

Figure 1. Retail-H Framework with the value-adding core processes (Becker & Schütte, 2004)

at the beginning, then falls just as strongly after reaching the peak. After an intermediate minimum, the curve rises again to a higher level of inertia. Mathematically, it is simply the decay after a jump excitation in the form of a strong, exponentially damped oscillation, with approximation to an equilibrium position around the jump, higher than at the beginning of the oscillation (Walker, 2017).

Figure 2. The Gartner Hype Cycle for 2017 (Walker, 2017) with the most relevant technologies for retailing

The Simple Hype Cycle is divided into five sections, according to this definition:

Innovation trigger:

The first phase is the technological trigger or breakthrough, is the start of the project or any other event that meets with considerable interest from the trade public. Free riders ascend to the new topic.

Summit of exaggerated expectations.

Peak of inflated expectations:

Technologies reach the valley of disappointments because they cannot meet all expectations and are quickly outdated. As a consequence, reporting is fading away.

Trough of disillusionment:

Although reporting on technology has declined sharply, realistic assessments are leading back to the path of enlightenment. The result, is an understanding of the advantages, the practical implementation, including the limits of new technology.

Slope of enlightenment:

A technology reaches a plateau of productivity when the benefits are generally accepted. The technology is becoming increasingly solid and is being developed further in the second or third generation. The final height of this plateau, strongly depends on whether the technology is adopted in mass or niche markets.

TECHNOLOGIES FOR RETAILING

The Hype Cycle is not industry specific and the given examples of application are randomly spread over all types of possible scenarios. The above outlined Handel-H-model is used to present the findings of the literature review regarding the existing applications of the proposed technologies for retailing. Each application is then matched with one or more value-adding core processes of a retail company.

Table 1. Upcoming technologies matched by area of use within retailing

Retail processes	Purchasing	Materials Planning	Goods Receipt	Invoice Verification	Accounts Payable	Warehouse	Marketing	Sales	Goods Issue	Invoicing	Accounts Receivable	Corp. Planning	Business Intelligence	Controlling	General Accounting	Cost Accounting	Human Resources
Technologies																	
Augmented Reality							X	X				X					
Commercial UAVs						X	X	X	X								
Blockchain				X	X					X	X		X	X	X	x	
Autonomous Vehicles		X				X			X								
Machine Intelligence	X	X	X			X			X				X	X			
IoT and IoT Platforms	X	X	X			X		X	X			X	X	X			X
Augmented Data Discovery				X	X					X	X	X	X	X	X	X	
4D Printing							X	X	X								
Smart Dust		X	X			X	X		X				X	X			
5G		X	X				X	X					X	X			

Our findings (see Table 1) show that there are 10 technologies that are applicable for one or more core processes:

Fifth-Generation Wireless and Mobile Communication Systems (5G)

Definition and delimitation

The fifth-generation (5G) wireless and mobile communication systems, were built in an attempted by the major industry players (from Alcatel-Lucent to Huawei) in order to align with an anticipated future (Monserrat et al., 2014). The prediction that the development is based on, comes to the conclusion that “it will be necessary to support 1000 times higher mobile data volume per area” (Cisco, 2014), and these “[...] requirements will go beyond the natural evolution of [current] technologies, which shows the need for a new mobile generation [...]” (Monserrat et al., 2014).

With 5G, the used spectrum of the mobile and wireless systems is broadened to higher-frequency bands (> 6 GHz) which allow the support of a much higher data rate-up, to several gigabits per second (Wang et al., 2014), compared to the predecessors.

However, the underlying architectural paradigm is also changing. Here, the 3rd Generation Partnership Project (3GPP), the regulating body working on the upcoming standards, defines three types of networking capabilities: enhanced mobile broadband (eMBB), massive machine-type communications (mMTC) and ultra-reliable, low latency communications (uRLLC). EMBB will allow the higher bandwidth needed, alongside a lesser latency. With uRLLC, this latency is even smaller, as uRLLC relies on millimeter wave (mmWave) spectrum bands (> 24 GHz), where very fast signals are possible. As the name obviously suggests, mMTC is about massive wireless access, by a large number of devices, and therefore, an enabler for the Internet-of-Things (IoT).

Areas of Application in Retail

The 5G systems will primary serve as a basis technology, enabling new operational purposes or enhancing existing ones. Here, the higher bandwidth alongside the possibility to connect a large number of IoT devices, will fuel the further application of 5G within retailing. Particularly, all scenarios that failed in the past (due to the lack of networking infrastructure), will get another chance.

Especially the tracking of the flow of goods will benefit by the revival. Here, the whole warehouse and logistic processes - from the receipt of goods, to warehousing goods issue – are areas of application. Fully transparent logistic processes in real-time are conceivable, which is of great interest, especially for multi- and omnichannel retailers.

Some argue that the diffusion of autonomous driving (Bönsch 2018), is only possible with the capabilities of 5G networks. Here, the full automation of all logistic processes is imaginable. Any application of virtual and augmented reality, was obstructed by the lack of a fast bandwidth. The extended data rate of 5G will improve the existing application of the VR technologies, for example: from IKEA, the kitchen sales process is noticeable. This is valid for local scenarios within the stores. In the past, an issue was the bandwidth of Wi-Fi was not sufficient for the parallel application of such applications, or on the customers' mobile devices.

Coming to mobile devices, 5G will enable a much broader utilization of wearable devices. These devices are allowed to have an independent network access, as less energy is needed, and will extend today's limited capabilities of many devices (like Google Glass). This influences the retail processes of marketing and sales in particular.

Examples of Prototypes or Existing Implementations

As the first prototypes of 5G networks are currently set up, only limited prototypes exist. The Fraunhofer Institute for Telecommunications built an initial prototype to use the extended bandwidth of 5G to enhanced virtual reality (Rommel, 2018). Here, the VR application, is able to stream the HD-videos that adapt in real-time to the user's movements.

Conclusion and Outlook for Retail Decision-makers

As 5G acts as the basis for many applications, it is clearly a technology to follow. However, for most retailers 5G will just become an IT commodity. Nevertheless, a commodity enabling and improving many use cases, which failed in the past, due to the lack of fast and reliable wireless and mobile internet access. Areas of use include: Materials Planning, Goods Receipt, Marketing, Sales, Business Intelligence and Controlling.

4D Printing

Definition and Delimitation

Recent developments have managed to add a new dimension to 3D printed objects. Printing in 4D, is a new process that enables a radical shift in additive manufacturing: "it entails multi-material prints, with the capability to transform over time, or, a customized material system that can change from one shape to another, directly off the print bed." (Tibbits, 2014). In this process, active materials (like shape memory polymers), can be printed to create an active microstructure within a solid structure (Zheng et al., 2014).

Areas of Application in Retail

A common example for this new technology, is childcare products that can react to outside temperature changes or humidity, for example. There are also use-cases for programmed, individual, self-deforming materials in healthcare, such as bio-compatible components that can be implanted in the human body.

For retailing, the area of application are similar to 3D printing (Vanderploeg, Lee, & Mamp, 2017): to produce customized products for consumers, produce in real-time and allow the customer to design and create their own goods.

Examples of Prototypes or Existing Implementations

So far, there are no existing implementations for 4D Printing, but you *can* find a lot of research and prototypes, for example, at the University of Wollongong in Australia, they have designed a 4D-printed water valve, which shuts when it comes into contact with hot water and it re-opens again, when the temperature subsides. The application of 3D printers is already tested by major companies. For example, the German fitness giant, ADIDAS is printing individual shoes for customers with 3D printers (Levi & Eichmann, 2004). Adding the fourth layer with self-deforming materials, that adapt to different under-grounds, is just a matter of time.

Conclusion and Outlook for Retail Decision-makers

4D printing can be judged as an advancement of 3D printing; to advance a lean, or just-in-time manufacturing and the individualization, for customers. Here, the type of goods is essential to the consideration of 3D and 4D printing. In fashion (see the example above), the need for individualization is high; for grocery and food retailing, it might be low. Areas of use include: Marketing, Sales and Goods Issue.

Augmented Reality

Definition and Delimitation

AR technology adds virtual objects, superimposed upon or composited with, the real world.

Therefore, “AR supplements reality, rather than completely replacing it.” (Azuma, 1997). Systems for Augmented Reality systems have the following three characteristics:

- Combines real and virtual
- Interactive in real-time
- Registered in 3-D

Virtual reality (VR), immerses a user in an imagined or replicated world, or simulates presence in the real world. In contrast to that, augmented reality (AR) adds only a digital layer to reality (Bellini et al., 2016).

Areas of application in retail:

AR-Technic can be used in retail, for example, within an app (Scholz & Smith, 2016). The Lacoste brand provides such an app to their customers, to try on shoes virtually, using AR technology. American Apparel uses an app to display information about a garment, Timberland uses Microsoft’s Kinect technology to try on different garments.

Examples of prototypes or existing implementations:

Several prototypes of Virtual/Augmented Reality technologies, are currently under development, or have already appeared on the market, such as: Microsoft HoloLens, Google Glass or the HTC Vive (Bellini et al., 2016).

Google Glass is a pair of glasses that expands reality by displaying data and information about the location. A sensor detects people, and displays information about them accordingly. It also allows activities, such as; reading books through glasses.

Various AR applications can support the tasks of employees. For example, the applications make it possible to work with free hands, while at the same time e.g., Google Glass displays the required information. In the automotive industry, this supports employees in their work-steps on the assembly line (Heun, Kasahara, & Maes, 2013).

Conclusion and outlook for retail decision-makers:

For marketing and sales activities involving the customer directly, this technology might serve as a great foundation to improve customer service and satisfaction, without the need to staff employees at the stores. It is also possible to extend the sales activity, towards the customers home directly. For service and communication intensive retail sectors, this might be a key technology. The areas of use include: Marketing, Sales and Corporate Planning.

Autonomous Vehicles

Definition and Delimitation

Autonomous Vehicles (AVs) are vehicles which “partially or fully drive themselves and which may ultimately require no driver at all” (Anderson et al., 2014).

There are five levels to classify automation (Anderson et al., 2014), from the status-quo of no automation, to the full self-driving automation. Here, the system takes full control of the vehicle. The driver is only necessary for entering the destination, they do not have to be available while driving.

Areas of application in retail:

One possibility for the use of AVs in retail, are the classical logistics and transportation processes (Heutger, Kückelhaus, Zeiler, Niezgoda, & Chung, 2014) and the warehouse operations.

It will not be long before the logistics industry deploys self-propelled vehicles on a large scale; the first applications are already in place. One of the reasons for this, is that logistics usually transports goods and not people, which often makes it easier to clarify legal issues. Many processes take place within private or on company premises. In addition, increased efficiency and safety, make autonomous vehicles interesting for the industry.

Examples of prototypes or existing implementations:

For many years, various companies have been working with unmanned vehicles in their warehouses to transport requested products. For public roads, the development is lagging far behind. Google's subsidiary, *Alphabet*, has been developing an autonomous driving system called, *Waymo* since 2009, which is expected to be launched in 2020.

Conclusion and outlook for retail decision-makers:

Autonomous vehicles will certainly have a great impact on any logistics process within retailing. Replacing the necessary human involvement, monetarizes as extensive reduction in one of the costs and labour-intensive processes in retailing. Alongside the advancement of the technology, autonomous vehicles will be available for serving the customer direct at their homes as well. Areas of use include: Materials Planning, Warehousing and Goods Issue.

Blockchain

Definition and Delimitation:

A block chain is a continuously expandable list of data sets, called "blocks", which are linked together by cryptographic methods. Each block typically contains a cryptographically secure hash of the previous block, a time stamp and the transaction data.

The term "blockchain" is used more specifically for a concept with which an accounting system can be kept on a decentralized basis, and yet a consensus is reached on the correct state of accounting, even if many participants are involved in accounting. This concept is called, *distributed ledger technology* (decentralized account book technology). It is thus, well suited for applications requiring transparency in records, with a permanent time and date stamp, such as titles, document histories, and notary services." (Lorenz et al., 2016).

Areas of application in retail:

A main area of application, is the processing of transactions and payments, since the technology enables more efficient processing of transaction processes, e.g., long transaction times can be avoided. According to a study (Accenture, 2015), the technology can be mature and an integral part of the financial system, by 2025.

Retailers can also benefit from blockchain technology. Blockchains can also be used in the public sector. This would allow public systems, based on blockchain technology, to manage and collect taxes or enable corruption-free and transparent elections (Schlatt, Schweizer, Urbach, & Fridgen, 2016).

DHL logistics uses blockchain technology to more efficiently handle transaction processes, thus, lowering costs (DHL, 2017). For retailers, there are three major areas of application: Supply Chain and Inventory Management (transparency between multiple constituencies, including; manufacturers, distributors, shipping carriers, insurers, importers, wholesalers and retailers), Payments and Accounting (customers complete transactions in cryptocurrencies, rather than traditional currencies), Loyalty and Rewards (blockchain offers real-time liquidity, making points more easily swappable between consumers and across retailers) and Advertising and Consumer Data (enabling collaboration between stakeholders and reducing fraud).

Examples of prototypes or existing implementations:

There are many examples of the utilization of this technology for retailing, such as:

Warranteer—A blockchain application that allows consumers to easily access info regarding the products they purchased and get service in the case of product malfunction.

Blockpoint—Simplifies the creation of payment systems and allows mobile wallet, loyalty programs, gift cards and other point-of-sale functionalities.

Loyyal—Uses smart contract technology in their loyalty and rewards platform, to create a more customized program that even allow for multi-branded rewards.

Conclusion and outlook for retail decision-makers:

Blockchain can serve as a commodity technology, replacing many legacy technologies. The challenge for decision makers will be, to find use cases where the advantages of this technology out-do long-trusted technologies. Mainly, processes between untrusted partners come into mind, but are rather rare in retailing.

Areas of use include: Invoice Verification, Accounts Payable, Invoicing, Accounts Receivable, Business Intelligence, Controlling, General Accounting and Cost Accounting.

Commercials UAVs (Drones)

Definition and Delimitation

Commercial “unmanned aerial vehicles” (UAVs), also known as “Drones”, are unarmed aircrafts, without a human pilot aboard. Either they fly under remote control by a human, or they fly autonomously, controlled by on-board computers. “UAVs range in size from large military drones with a wingspan of nearly 200 feet, to commercially available, inch-wide micro drones. Their ranges of flight vary, with some commercial drones being confined to a few feet away from the operator, to advanced military drones that can fly for over 17,000 miles, without having to land” (Rao, Gopi, & Maione, 2016).

Areas of application in retail:

The field of application is wide. They are already use to; “survey crops, in search and rescue operations, to count wild life and keep track of animal population, in land surveying, to survey forest fires, to inspect oil pipelines, power lines and other remote infrastructure (Rao et al., 2016). There are also various applications for commercial UAVs in retail. One of the best areas of application, was the delivery of minimal parcels and packages. This area has enormous potential, including the positive impact on CO2 emissions or the obstruction of delivery due to traffic jams. In addition, the personnel costs will be *drastically* reduced nationwide, *if* the drone replaces the people in this area. In the near or distant future, the market leaders in mail order, will offer a delivery service by drone.

Examples of prototypes or existing implementations:

Amazon is currently conducting experiments with Prime Air in the USA, to deliver minimal packages to customers in less than 30 minutes. DHL has already started a test run, in Europe, with the “Parcelcopter”.

Conclusion and outlook for retail decision-makers:

As autonomous vehicles, drones will have an impact on many logistics processes. Contrary to the first-mentioned vehicles, drones can first of all, be used for serving the customer directly. Areas of use include: Materials Planning, Warehousing and Goods Issue.

Augmented Data Discovery

Definition and delimitation:

Augmented Data Discovery (ADD) describes tools that allow the user to visualize, analyze and analyze data in the simplest way without the help of IT or data experts. ADD technology consists of at least two components: Augmented Data Preparation and Augmented Analytics (Smarten, 2018).

Augmented Data Preparation helps users access data, integrated from varied data repositories and sources in a single interface, so they can test theories and hypotheses. These tools give users access to crucial data and information and connect to data sources.

Augmented Analytics automates data insight by utilizing Machine Learning and Natural Language Processing and automates data preparation, so users can share crucial data and make educated decisions. With an advanced augmented data discovery solution, the organization can share, manipulate and present data, with clear results and access to sophisticated tools. These tools ensure that the organization makes decisions based on fact rather than opinion.

Areas of application in retail:

Practically the same as existing Business Intelligence Solutions, just adding real-time reporting. This could be used for fraud detection, customer feedback processes or gaining insight for professionals, except IT-oriented, users.

Examples of prototypes or existing implementations:

There are still very few intuitive tools that can be understood as ADD software. One of the best known and most used solutions in this area, certainly offers Tableau with its software suite.

Conclusion and outlook for retail decision-makers:

This technology can support better decision-making processes within retail. Also, the dependencies on key employees (these with the knowledge in data analytics), can be massively reduced. Areas of use include: Invoice Verification, Accounts Payable, Invoicing, Accounts Receivable, Corp. Planning, Business Intelligence, Controlling, General Accounting and Cost Accounting.

IoT and IoT Platforms

Definition and delimitation:

The internet refers to a world-wide network to connect objects that are uniquely addressable, based on standard communication protocols, so that these objects are able to interact with each other, in order to achieve: smart recognitions, positioning, tracing, monitoring or administration. The difference between IoT based systems and personal computers or smartphones, is that a human can control the IoT devices, but it's not necessary. This is because IoT systems are capable of operating autonomously and to adapt themselves to a specific situation.

IoT platforms are software products offering comprehensive sets of application-independent functionalities, that can be utilized to build individual IoT applications (Wortmann & Flüchter, 2015). Providers of IoT platforms (such as: Google, Amazon, Microsoft or SAP) focus on different aspects of the IoT technology in order to support their customers. In general, there is no standard for IoT platforms, but various individual IoT platforms with individual technology stacks.

Areas of application in retail:

According to Accenture and (Gregory, 2015), IoT can be used in three critical areas of the retail business: customer experience, the supply chain, and new channels and revenue streams. Predictive maintenance can be used for managing energy, failure or detecting other issues. Moving merchandise

more efficiently is one of the goals that can be achieved with IoT in logistics. Many retailers have been using GPS to track and route trucks in the past. IoT offers a much higher degree of accuracy and can track even a single product or package from the logistics center, to the individual checkout by a customer.

Examples of prototypes or existing implementations:

When Ocado launched its automated packaging service in February 2016, it was the largest of its kind. With the help of a RFID system, Ocado has been able to control and coordinate the movements of *millions* of grocery store items, and thus speed up the logistic processes, when an online order is placed.

In 2015, Levi's partnership with Intel, resulted in a "Proof of Concept", with the goal of delivering near real-time inventory monitoring for stores in San Francisco. The concept is now marketed as; "Intel Retail Sensor Platform".

Over 4,000 beacons are currently installed in 700 Macy's stores. This is part of a broad corporate investment strategy in Omni-Channel retail technologies. It allows to push notifications to customers, based on their current location.

Conclusion and outlook for retail decision-makers:

The IoT-devices and platforms will not bring a benefit by itself, but rather act as basis for many "build-upon" applications, enabling many use cases. Especially the interaction with machine learning and augmented data discovery; this will be of the most potential in retailing. Areas of use include: Purchasing, Materials Planning, Goods Receipt, Warehousing, Sales, Goods Issue, Corp. Planning, Business Intelligence, Human Resources and Controlling.

Machine Intelligence and Learning

Definition and delimitation:

Machine learning (ML) is a generic term for the "artificial" generation of knowledge from experience. An artificial system learns from examples and can generalize them *after* the learning phase is completed. This means that it does not simply memorize the examples, but "recognizes" patterns and laws within the learning data. Thus, the system can also evaluate unknown data (learning transfer), or fail to learn unknown data (over-adaptation). There is a wide range of possible applications, these include: automated diagnostic procedures, credit card fraud detection, stock market analysis, nucleotide sequence classification, speech and text recognition, and autonomous systems.

Areas of application in retail:

ML has great potential in areas such as forecasting or strategic optimization, and can be used across industries.

(Henke et al., 2016) has, "identified more than 300 specific use cases, across 12 industries". For example, in healthcare, the systems can diagnose diseases on the basis of various data, while logistics is supported by route optimization. ML in retailing can, for example, help businesses to order the right quantity of goods, by analyzing demand based on various factors.

Examples of prototypes or existing implementations:

Amazon uses ML by analyzing the customer's data, drawing conclusions about the customer's interests, and making suggestions for further purchases accordingly. Walmart's use of ML in brick-and-mortar stores, is very similar to the "Amazon Go" concept store, which combines computer vision, machine learning, and sensors to bypass the checkout process entirely. By using ML, Blue Yonder optimizes the ordering and replenishment of brick-and-mortar stores. ML also makes it possible to regulate prices by analyzing demand.

Conclusion and outlook for retail decision-makers:

This technology can fully automate and provide an optimized decision making within retail. As many processes in the area of application lack any IT-support, and are fully handled manual today, the potential is huge. Areas of use include: Purchasing, Materials Planning, Warehousing, Goods Receipt, Goods Issue, Controlling and Business Intelligence.

Smart Dust

Definition and delimitation:

The intention of Smart Dust is to build low-power computers, within a cubic millimeter mote to allow for an integrated, massively distributed, sensor network. Smart Dust requires massive advances in “miniaturization, integration, and energy management.”. Designers can use microelectromechanical systems to build small sensors, optical communication components, and power supplies; whereas, microelectronics provides increasing functionality in smaller areas, with lower energy consumption (Warneke, Last, Liebowitz, & Pister, 2001).

Areas of application in retail:

Original projects are mostly research-based: deploying defense networks rapidly by unmanned aerial vehicles, monitoring environmental conditions that affect crops and livestock, and managing inventory control or monitoring product quality.

Examples of prototypes or existing implementations:

Hitachi has developed the world’s smallest and thinnest Radio Frequency Identification (RFID) chip. It is the size of only 0.15 x 0.15 millimeters, and is 7.5 micrometers thick. There is no known application or use of this project within retail, yet.

Conclusion and outlook for retail decision-makers:

Smart Dust is in a too early stage of development, to say something about the implications for retail. However, as soon as the chip industry overcomes the present technical and physical limitations, the impact will be huge. Especially in the logistics processes; the Smart Dust Technology might deliver the promises that RFID did not.

Areas of use include: Materials Planning, Goods Issue, Warehousing, Goods Received, Marketing, Business Intelligence and Controlling.

FUTURE RESEARCH DIRECTIONS

From a scientific perspective, the Hype Cycle Model is not a verifiable model, as many empirical (bibliometric) studies, verify or reject its forecasts (Dedehayir & Steinert, 2016; Jarvenpaa & Makinen, 2008; O’Leary, 2008).

Following this article, there is need for further research in terms of judging the potential of new technologies for different domains and industries, as the author does not see a general applicability, of any new technology, for any possible field or industry. This focus is not the intention of the Gartner model, but for a profound judgment, a domain-oriented perspective is indispensable.

The other large field of possible further research, is about developing the right strategy to adopt a new technology. Just to adopt technologies at the end of the cycle (arriving at the ‘Slope of enlightenment’), is not the way to follow, as you are losing any first-mover advantages. Finding the right spot, might be individual for each company, domain or industry. So far, not much research, especially for retailing, on these questions has been conducted.

CONCLUSION

Gartner's Hype Cycle is a technology life-cycle model, that has already been established in practice and is relevant to many industry managers. It serves good to describe, explain and forecast technological or market-relevant developments. It provides insights into subjectively perceived market expectations, as well as the technology or market maturity of the object under consideration.

As the literature review shows, see Table 1, is the major adoption of digital technologies present within the already IT-focused parts of retailing and wholesaling. The business processes of controlling, business intelligence and marketing are always for a high penetration of advanced technologies. Therefore, it is not odd that the future adoption of digital technologies is seen in these process areas. Other cost sensitive processes like logistics are target of digitalization because of the huge potential of cost savings.

Especially in view of increasing external influences such as: globalization, dynamic market and environmental conditions or shorter product and market life cycles; the Gartner Hype Cycle is an important tool for companies with regard to strategic decisions. It can help with technology strategy or investment decisions. The information, categorizations and descriptions are not transparent or imprecise enough for empirical and scientific verification.

Managers should use internal and external technology, as well as market knowledge, to extend and adapt the model against the background of the model's weaknesses. The information from the model, can then be used as guidelines for strategic decisions, but should *not* be used as the sole criterion for decisions.

For retailers in general, not all new technologies that are hyped, sustainable. As the domain is very unique, it is always needed to check the fit of an upcoming technology, for their use cases within retailing.

KEY TERMS AND DEFINITIONS

4D Printing: Multi-material prints, with the capability to transform over time, or a customized material system that can change from one shape, to another.

5G: The fifth-generation (5G) wireless and mobile communication systems, which uses a much broader spectrum and higher-frequency bands, which allow the support of a much higher data rate up, to several gigabits per second.

Augmented Data Discovery: Tools that allow the user to visualize, analyze and data in the simplest way, without the help of IT or data experts.

Augmented Reality: A technology adding virtual objects, superimposed upon or composited in the real world.

Commercials UAVs (Drones): Unarmed aircrafts, without a human pilot aboard.

Gartner's Hype Cycle: A technology life-cycle model.

Internet of Things (IoT): A type of network to connect anything with the Internet, based on stipulated protocols, through information sensing equipment, to conduct information exchange and communications, in order to achieve smart recognitions, positioning, tracing, monitoring, and administration.

Machine Intelligence and Learning: A generic term for the “artificial” generation of knowledge from experience.

Smart Dust: Low-power computers within a cubic millimeter mote, to allow for an integrated massively distributed sensor network.

eLancing the Future Work Model: Opportunities and Challenges

INTRODUCTION

Technology has penetrated our lives, this permits it to be a key changer and shaper of our daily activities. Evidence of the growing influence that technology has in our lives can be seen by the number of internet users worldwide estimated to be 4 billion users (Internet World Stats, 2017). In general, digital platforms can be an information analysis platform (i.e., online reviews), capital platform (i.e., facilitate the sale or rent of assets) and labor platform (i.e., links client-online freelancers). Firms are now repositioning their production strategies towards a distributive system, this explains why some high-tech firms remotely outsource talent from global labor markets (Cascio & Aguinis, 2008). Work is not just central to how we contribute to and participate in the society, but also a powerful mechanism for economic inclusion and social identification. Advances and progress made in technological gave rise to a new labor market mechanism known as electronic lancing (eLancing) as noted by Abubakar and Shneikat (2017). In eLancing is a type of work arrangement that takes place in the cyber platform in which individuals and/or client organizations hire other individuals (i.e., freelancers/sellers/workers) for lucrative assignments and/or work (Abubakar & Shneikat, 2017).

The eLancing platform resembles the eCommerce platform, the demarcating line between the two is that eLancing is a computer-mediated platform (market place) to advertise vacancy/demand, recruit, select, hire and compensate/pay virtual workers as oppose to the buying and selling of goods and services. eLancing platform is an online platform where online freelancers are connected through the internet to provide various services (Shneikat, 2016). Virtual workers are the eLancers, (i) who work without meeting or knowing the employer, (ii) work on microtasks lasting for specific hours and paid on hourly basis or fixed amount within a given period, (iii) do not have the traditional work schedule 9 to 5, and (iv) do not report to anyone (i.e., unit chief or supervisor). Example of such platform includes: upwork.com, guru.com, fiverr.com, freelancers.com and many more. The world largest eLancing platforms are upwork.com and freelancer.com. Upwork has 12 million registered eLancers with 3 billion jobs posted annually and more than US\$1 billion worth of work done annually (Upwork, 2017). The Freelancer has 27 million registered eLancers with 13 million jobs posted and more than US\$588 million worth of work done annually (Freelancers, 2017).

Technology and talent management are the main forces pushing for change in the human resource management in the 21st century. Modern scholars (Abubakar & Shneikat, 2017; Cascio & Aguinis 2008) claimed that present staffing and work models does not match with the present fast-paced work systems and organizations. The traditional way in which labor and capital are organized for production and service delivery in one physical location seems to be losing appeal. Artificial intelligence, robotics, augmented and virtual reality, and the internet of things have been linked to digitalization and the 4th

DOI: 10.4018/978-1-7998-3473-1.ch090

industrial revolution. However, it is about us “humans” - the way we live, learn, earn and play. Thus, the future of work is all about pliability and the ability to reinvent oneself. The orthodox archetype of having a stable life time job is eroding and is being replaced by more flexible short-term precarious work arrangement, the eLancing.

Technically, eLancing represents the resurrection of dead capital, the comatose human capital in the context of the World Wide Web’s genealogy. Our values, norms, cultural institutions, and educational systems were designed to create traditional workers. eLancing work model has the propensity to alter the traditional work perceptions, norms, institutions and regulations. This new baby of digitalization and the 4th industrial revolution, eLancing, calls for further examinations, new policies, work practices and theory development and revalidation of existing theories. Thus, this chapter’s aim is to provide a comprehensive overview of existing work models and potential future work model. Subsequently, in this chapter analogy of various work arrangements ranging from independent professionals, contracted professionals, outsourcing and offshoring, teleworking, crowdsourcing and eLancing was conducted. This chapter also classifies eLancers based on several socio-demographic factors, describes the challenges, opportunities and implications of eLancing.

BACKGROUND

Hybrid Work Models

Hybrid and flexible work models are designed to allow individuals work from home, work outside regular office hours, to reduce or extend contract hours (Groen et al., 2018). These practices make employees to perform all work-related duties at a remote location and any time of day. The common theme linking independent professionals, contracted professionals, outsourcing and offshoring, teleworking, crowdsourcing and eLancing is work (Aguinis & Lawal, 2012; Shneikat, 2016). Prior researchers often interchangeably use these terminologies; however, they have several distinguishing features. This section will provide a more nuance understanding of each work arrangement:

Independent Professionals

An independent professional or contractor are self-employed persons who do not have any employees but can provide goods and services to other entities under terms specified in a contract or within a verbal agreement (Sayah, 2013). Conventional workers or temporary workers are under the directives and control of the hiring firm. However, independent professionals are not controlled by the client, because client’s control is limited to accepting or rejecting the outcome (Connelly & Gallagher, 2006; Fragoso & Kleiner, 2005). Independent contracting shares several similarities with eLancing. *One*, working alone on a project-related basis for various clients, either in parallel or in succession, project pay, and other details is governed and regulated by a contract. *Two*, as with eLancing, the client does not supervise the professionals directly the professionals have leeway in terms of hours of work and location. The demarcating line with eLancing includes; one, independent professionals face constraints based on clients’ needs e.g., new workplaces, conditions and locations (Sayah, 2013; Süß & Kleiner, 2010). However, eLancers can have specific working conditions e.g., hourly rate, fixed amount, milestone, and do not face new conditions or location since they work online. A freelancer (e.g., plumber, carpenter, auditor, former employee) can be an independent contractor, but an independent contractor is not an eLancer

(Connelly & Gallagher, 2006). *Three*, eLancers work online, while independent professionals can work both online and offline. *Four*, independent professionals work arrangement is governed by two parties (i.e., the professionals and the client organizations), while eLancing is governed by three parties (i.e., eLancer, the platform, and the client).

Contracted Professionals

Contracted professionals are individuals or micro-group who execute special duties and tasks inside the physical location of the client firm, state or region, usually on demand, for a specific amount and time. The contract can be either vendor-on-premises or co-employment arrangement. In vendor-on-premises arrangements, the responsibility for managing and protecting workers, and work regulations is transfer to the contracted professionals. In co-employment arrangements, the responsibility for managing workers is shared, while, workers protections and work regulations is transfer to the contracted professionals (Kuhn & Maleki, 2017). Contracted professionals differ from eLancing as professionals can work both offline and online. *Two*, contracted professionals entail two parties (i.e., the professionals and the client organization), whereas, in eLancing there are three parties (i.e., eLancer, the platform and the client). *Three*, work process is controlled by the contracted professionals as the client organization mostly have limited know-how on the specialization. *Four*, contracted professionals somehow engage in temporary jobs which typically lack the job security, fringe benefits, and possibilities for advancement that are available to incumbents of permanent job, however, eLancing is time or task based which gives no room for further implicit expectations neither from eLancers or from the client organization.

Outsourcing/offshoring

Outsourcing is an agreement in which a firm delegate some of its business process and operational, and/or non-core functions to another party. Aguinis and Lawal (2013) argued that offshoring and outsourcing are similar, the only designated difference is that offshoring requires that outsourcing be sent to another country. Outsourcing/offshoring and crowdsourcing are similar, as both utilize external human capital and resources to accomplish internal activities (Afuah & Tucci, 2012). Outsourcing/offshoring differs from crowdsourcing and eLancing on several fronts. *One*, in crowdsourcing, undefined number of individuals are recruited to solve business problems (Howe, 2006), as oppose to eLancing and outsourcing/offshoring where only selected vendor (Ye & Kankanhalli, 2015) and eLancer are recruited (Abubakar & Shneikat, 2017). *Two*, in outsourcing/offshoring and/or eLancing, client can monitor the development of the solution to ensure desired quality. Howbeit, the quality of business solutions acquired through crowdsourcing is questionable as solvers might not be professional (Poetz & Schreier, 2012). *Third*, crowdsourcing has solution diversity, while eLancing and outsourcing/offshoring does not (Ye & Kankanhalli, 2015). *Four*, in outsourcing/offshoring individuals follow the directives of the client. Whereas, in eLancing, eLancers are paid based on the given task, choose what tasks to work on and have little or no interaction with their client. *Five*, outsourcing/offshoring is governed by two parties (i.e., the outsourcer and the service provider), while eLancing is governed by three parties (i.e., eLancer, the platform, and the client).

Teleworking

Individuals who engage teleworking work arrangement are referred to as ‘teleworkers’, ‘commuting-based workers’ and ‘home-based workers’. The generic term ‘teleworker’ delineates an individual or group of individuals who work at a place other than the physical workplace facilitated by the Internet technology at a scheduled hour. Bailey and Kurland (2002, p. 384) defined teleworking as, “working outside the conventional workplace and communicating with it by way of telecommunications or computer-based technology.”. Gajendran and Harrison’s (2007) meta-analyzed 46 empirical and theoretical papers associated with teleworking and then coined a true definition for the activities. An alternative work arrangement in which employees perform tasks elsewhere that are normally done in a primary or central workplace, for at least some portion of their work schedule, using electronic media to interact with others inside and outside the organization (Gajendran & Harrison’s 2007, p. 1525). In essence, telework constitutes an early form of virtual work, long before hypermedia and rich media emerges (Aguilera et al., 2016; Hunton & Harmon, 2004). Thus, teleworking precedes crowdsourcing, and eLancing. Human, social and organizational arguments have been prescribed as the drivers of teleworking e.g., time saved in commuting, rational, cost-effectiveness, schedule flexibility, freedom from interruptions, reduced pollution, work-family enrichment strategy (Harker-Martin & MacDonnell, 2012). Whereas, professional, social isolation and reduced psychological health are cited as challenges (e.g., Aguilera et al., 2016; Coenen & Kok, 2014; Giovanis, 2018; Hunton & Harmon, 2004).

Teleworking spans into several work domains ranging from hospitality and tourism, telemedicine for doctors and nurses etc. Teleworking differs from eLancing on several fronts. *One*, teleworkers have a conventional relationship with one employer or firm; while eLancers do not work exclusively for one employer or firm (Shneikat, 2016). *Two*, eLancers do not report the specific hours that they work for a specific employer and they do not negotiate the teleworking arrangement. Consequently, eLancers telework 100% of their time, whereas, teleworkers can work in firms’ physical location and telework as well. *Three*, in teleworking there are two parties (i.e., employee and hiring organization), whereas, in eLancing there are three parties (i.e., eLancer, the platform and the client). *Four*, Aguinis and Lawal (2013) contend that in teleworking: (i) teleworking frequency (ii) teleworking time arrangement e.g., fixed or flexible schedule, (iii) teleworking location e.g., home or satellite station, and (iv) teleworking decision e.g., firm decision or teleworkers decision and initiative. These four facets distinguish teleworking from eLancing, as they are not applicable to eLancing.

Crowdsourcing

According to Howe (2006, p. 1), crowdsourcing is the act of “outsourcing organizational task to an undefined (and generally large) network of people in the form of an open call”. This definition has been criticized and redefined as “the use of IT to outsource any organizational function to a strategically defined population of human and non-human actors in the form of an open call” by (Kietzmann, 2017, p.152). Crowdsourcing as a concept, amalgamates ‘crowd and outsourcing’. The central idea is to distribute work, generate ideation and critical thinking, vote in favor of the best alternatives culled from crowds (Ikediego et al., 2018; Prpić et al., 2015) to produce optimal and superior results (Majchrzak & Malhotra, 2013). Crowdsourcing is an online and distributed problem-solving model (Brabham, 2008), in which organizations (i.e., Amazon Mechanical Turk, InnoCentive, Dell IdeaStorm, and TaskCN) target crowds and request for contributions to develop business solutions. Perhaps, just as businesses and their problems vary, so do the types of crowds and contributions they can offer the firm. In this view, busi-

ness enterprises can build crowd capital through crowdsourcing by adopting a top-down process to seek bottom-up resources (e.g., expertise, know-how and opinions) from the crowd (Aitamurto, Leiponen & Tee, 2011; Prpic & Shukla, 2013). This occurs in as a three-stage model: (i) constructing a crowd, (ii) developing crowd capabilities, and (iii) harnessing crowd capital for the benefit of the organization. Liu, Yang, Adamic and Chen (2014) highlighted that in crowdsourcing marketplace, businesses/enterprises post business problems and then problem solvers (i.e., the crowds) enroll and partake in solving the business problem to gain rewards (by competing with other solvers). While the firm gets business solutions that is approved by crowds (i.e., potential consumers) and at a lower price. Crowdsourcing differ from eLancing in several dimensions.

One, crowdsourcing is outsourcing whereby the workers doing the tasks are recruited through the Internet, whether or not the actual work is done online—although in the vast majority of cases it will be. Whereas, eLancing is basically executed in a computer-mediated platform (Schmidt & Jettinghoff, 2016). *Two*, crowdsourcing is operationalized with individuals willing to do micro-task for little returns (Ikediego et al., 2018), as oppose to eLancing where task can be micro or macro and is executed by the eLancer (i.e., individual, group or small firm). eLancer has the luxury to bargain for price and milestone, whereas, the crowd only follows client directives (i.e., individual or organization). *Three*, although, outsourced business problems and activities are performed both in eLancing and crowdsourcing platforms. However, eLancing “constitute of an individual or group of individuals who work independently for a client; while in crowdsourcing, the work is done collectively” (Abubakar & Shneikat, 2017; Aguinis & Lawal, 2012; Prpic’ et al., 2015). From relational taxonomy view, eLancing constitute of three parties (eLancer, the platform and the client) and one business solution. While, crowdsourcing constitutes of multiple parties (crowd of people, the platform and the client) and multiple business solutions. *Four*, in crowdsourcing, the client (i.e., client, business owner or employees) operate in crowdsourcing platforms to specify business problems and requirements, monitor, provide feedback and rebuttals, and nominates final business solutions (Sieg, Wallin & Von Krogh, 2010). Contrariwise to crowdsourcing fundamental objectives (i.e., lowering business solution cost), these activities may incur costs (i.e., resources, time and effort) for businesses (Ye & Kankanhalli, 2015). Even though the fundamental objectives of eLancing and crowdsourcing are the similar, clients have minimum level of involvement in eLancing, thereby saving scarce resources, time and efforts.

FOCUS OF THE ARTICLE

Electronic Lancing (eLancing)

eLancing is a process in which client organization delegates task to individuals, group, or small-sized firms interested in being hired online. More subtly, “organizations/individuals (i.e., clients/buyers/requesters) access other individuals (i.e., freelancers/sellers/workers) for remunerative tasks of varying temporality and complexity with commensurate qualifications and returns” (Abubakar & Shneikat, 2017; Green et al., 2014). Thus, “eLancers and their clients are spatially dispersed strangers from across the globe, interactions, which are short-term, occur virtually and largely asynchronously, relying on written communication” (Abubakar & Shneikat, 2017; Kneese et al., 2014). According to Abubakar and Shneikat (2017) and D’Cruz, and Noronha (2018), “registered eLancers and clients are linked only via projects conducted on the platform or discussion fora provided by the platform. Interactions occur via synchronous and/or asynchronous text messages and rich media (i.e., audio, video clips and conference)”.

eLancers compete for jobs via bidding, clients select the best bidder via several metrics (i.e., rating, number of successful projects, earnings if visible and reviews). The eLancing platforms stipulates commissions on every project, ensures supportive work atmosphere, performs authentication check, resolve conflicts, borderless nature, and bears no legal, financial or any sort of liabilities towards clients and eLancers (Caraway, 2010; D’Cruz & Noronha, 2016). Abubakar and Shneikat (2017) advocated that eLancers engage in eLancing activities primarily for autonomy, flexibility and work-family balance. Others are driven by economic circumstances and labor market conditions (i.e., high returns; unemployment, geographical location, equality and disability) and personal factors (i.e., skills development, reputation, passion, enjoyment in problem-solving, trust, and transparency). Bughin, Manyika and Woetzel (2016) further argued that eLancers can be taxonomized into four, based on several demographics, socio-economic and socio-psychological needs namely:

- **Free agents** – unemployed, eLancing is the primary source of income and actively prefer eLancing work style.
- **Reluctants** – unemployed, eLancing is the primary source of income, but would prefer a traditional job.
- **Casual earners** – employed individuals, eLancing is a supplementary source of income and eLance by choice or as a hobby. The primary motivation to work is often social, pleasure, fun, derived satisfaction and not money.
- **Financially strapped** - employed individuals, eLancing is a supplementary source of income, but would prefer not to eLance. The primary motivation is money and to save up for a rainy day (Bughin et al., 2016). See Table 1 for more details.

Table 1. eLancing/eLancers Matrix

eLancing is my....	Primary Income	Supplemental Income
Preferred Choice	Free Agents Primary source of income Willingly choose eLancing work style Not employed in traditional jobs Example: Students, freelancer, and others	Casual Earners – The Hobbyist Supplement source of income Willingly choose eLancing Some have traditional primary jobs Example: Students, retirees & others
Necessary Choice	Reluctants Primary source of income Prefer traditional jobs Example: A fresh graduate looking for job	Financially Strapped Supplement eLancing out of necessity Prefer not to eLance Example: Low wage translator

SOLUTIONS AND RECOMMENDATIONS

eLancing Opportunities

Critics argued that digitalization, artificial intelligence (AI) and robotics will take over our jobs. It is important to recall that our forefathers also feared massive technological change. AI and robotics might wipe off today jobs, but it is more difficult to know what jobs will be in demand in 30 years. AI and robotics have created more jobs—not fewer e.g., engineers, AI specialist and data scientist. Digitalization and AI will create more jobs, not mass unemployment if we responsibly guide innovation ~claims tech leader Elon Musk.

Consequently, the intersection of AI and eLancing work arrangements led us to scrutinize smart services. Smart services are strictly based on field and artificial intelligence (Dreyer et al., 2019), which denotes the ability of machine to assist human activities through the seamless use of pervasive computing (Clay, 2018; Korzun et al., 2018). Online smart rooms are known as enhancers and facilitators for distributed and online collaboration (Rogers & Lindley, 2004). In the context of eLancing, smart services are prevalent in smart rooms which improve and facilitate collaboration between several client organizations and eLancers. For instance, chat panels, conference calls, video conferencing, file sharing etc. Thus, eLancing offers a suitable environment that supports to support a collaborative and remote activities. In addition, smart services co-create value by the eLancers and client organization via eLancing platforms and machine intelligence. eLancing is one of these innovations, it has bunch of opportunities and benefits to offer to both eLancers and client organizations. Amongst them are:

For eLancers

Greater returns and earnings - eLancing offers exciting job opportunities e.g., writing, translations, social media management, developing algorithms for machines and robots. eLancers can access international and competitive market across globe. The future will not be a matter of human versus machine, but rather machine and human working in tandem to solve the business problems. eLancing is expected to play an important role. Individuals can earn more than the national average.

Institutional trust and transparency - is one factor that distinguishes eLancing from traditional contracting, outsourcing/offshoring and crowdsourcing work arrangements who cite difficulties collecting the money and wage theft (Kuhn, 2016). For instance, in MTurk clients are free to withhold payment without explanation for any work they find unsatisfactory. Similarly, Amazon does not provide a channel for workers to rate clients or comment on their transaction experiences. Whereas, eLancing marketplaces offer escrow and dispute resolution services (eLancing court), to facilitate and reduce unfair transactions and allow workers to collect their money and rights in case of dispute. Moreover, eLancers and clients can rate and comment on each their experience (managed by the platform), this would facilitate the decision of a potential client or eLancer.

Opportunity to grow – emergence of robotics and AI, and hybrid work models like eLancing implies that work and workforce must be redefined. Work should be reengineered because technology has and will reshape every job through alternative work arrangements. In this regard, individuals will engage in lifelong learning, oversee their destiny and career path, and pursue their passion.

Autonomy and flexibility - eLancers have the luxury to work from their beds, in their pajamas, and coffee shops, and spend more time with family. If the remote work system is to become a norm in the future, eLancers can choose to live in a tech-friendly city, thus, future talent war might be between cities and not companies.

Geographical barriers breaker - throughout history, geography profoundly shapes labor markets, in that employees must to live in proximity with the productive capital and other factors of production. The beauty of eLancing is that it has remove the barriers of geography (Clemens, 2011; Chen, & Horton, 2016). eLancers can work from anywhere, anytime in the world.

Equal employment opportunity – eLancing platforms to some extent offer economic inclusion for individuals who do not hold the educational qualifications necessary to secure a decent job in the local labor markets. Similarly, disabled, less privilege individuals (i.e., minorities) have access to work opportunities (Graham, Hjorth & Lehdonvirta, 2017).

Table 2. eLancing opportunities individuals/eLancers

eLancers
Greater returns and earnings
<i>Example:</i> eLancers can earn more money compare to traditional work setting. For instance, Indian computer programmers who work as eLancers can earn up to 5 times the national average.
Institutional trust and transparency
<i>Example:</i> eLancers and client organizations work based on trust, as eLancing platforms such as Upwork have integrated “escrow” to serve as safe net and to avoid conflict of interest among the parties. Online reviews are known to influence business decisions. Upwork platform allows parties to comment on each other’s performance and share their experiences through rating and online reviews. resolution center is also available to solve disputes between client organizations and eLancers.
Opportunity to grow
<i>Example:</i> eLancing provides individuals with opportunities to grow through challenging and task diversity.
Autonomy and flexibility
<i>Example:</i> eLancing provides individuals with autonomy to choose what, when, where and how to work.
Geographical barriers breaker
<i>Example:</i> eLancing has eliminate geographical barriers, in that individuals across the globe can sign-up and work.
Equal employment opportunity
<i>Example:</i> eLancing ensures that everyone including disabled and minorities have access to work opportunities.
Protection
<i>Example:</i> eLancers are not susceptible to workplace accidents and injuries as applicable to normal work.
Short term insurance / safety net
<i>Example:</i> eLancers can choose to be insured e.g., Trupo
For firms and client organizations
Client organizations can benefit from the eLancing work arrangements in various ways. Examples are summarized in table 3.

Protection - eLancers are not susceptible to workplace accidents and injuries as with independent and professional contractors who are vulnerable to lack of paid sick days, not covered by antidiscrimination employment legislation and safety net programs (Kuhn, 2016).

Short term insurance / safety net - Trupo is the first short-term disability insurance designed specifically for eLancers, who have the freedom to decide how much of their average income to insure by paying a monthly premium. In return, if an illness or injury keeps them away from working for more than a week, Trupo kicks in and sends you up to 50% of your normal income for up to three months. Table 2 summarize the benefits of eLancing for eLancers.

Numerical flexibility – with eLancing client organization has the luxury to adjust the number of eLancers they work with, the type of work, amount to be paid and the number of hours to be delegated workforce size, or the number of hours worked, in response to changes in product demand.

Functional flexibility – eLancing platforms provide access to individuals with expertise and highly specialized skills, thus, client organization can easily complement the capabilities of their in-house employees on an on-demand basis with high pliability.

Financial flexibility – Apart from numerical and financial flexibility, eLancing platforms can provide client organizations with financial flexibility. In that, hiring is on-demand basis and financial status basis, and access to eLancers with specialized skills and expertise.

Table 3. eLancing opportunities for client organizations

Client organizations
Numerical flexibility
<i>Example:</i> Downside eLancers at any time especially during off-season.
No accrued worker compensation as applicable to traditional work setting.
Functional flexibility
<i>Example:</i> Hire eLancers on demand thereby reducing cost of maintaining workers.
Financial flexibility
<i>Example:</i> eLancing reduces overhead for organizations.
Eliminates traditional hiring barriers
<i>Example:</i> eLancing eliminates the cost of searching, hiring, and even insurance. eLancing allows firms to hire individuals anyway in the World, technically bypassing governmental and bureaucratic pressure and cost.
Reduces start-up and transaction costs
<i>Example:</i> eLancing eliminates the cost of training, orientation, medical test (new employees) as well as reduces time frame.
eLancing Challenges
Everything good comes with challenges, eLancing has several challenges that need urgent adjustment in managerial and practical policies:

Eliminates traditional hiring barriers – eLancing platforms facilitates the hiring process, eliminate or at least reduce geographical, informational, and administrative barriers in the hiring process. In this regard eLancers, can be used for short term projects, on demand basis. With eLancing platforms, firms can have access to varieties of skill sets, individuals with varying degree of work histories, educational and cultural backgrounds who likely to create knowledge that will be useful for innovation (Corporaal & Lehdonvirta, 2017).

Reduces start-up and transaction costs - eLancing platforms is a way to reduce firm's start-up and transaction costs in all fronts. In that client organization can hire eLancers quickly to address project needs and also adapt faster to environmental changes (Corporaal & Lehdonvirta, 2017).

Economic policy - the growth in eLancing work model raises issues on the economic front. In fact, the in and out of eLancers in response to projects demands makes the economy's labor supply procyclical. This causes discrepancy and understatement of unemployment rate in recessions and employment rate after economic expansions.

Production and tax – the present economic policy does not take eLancers willingness to work extra hours or employed individual's willingness to earn from eLancing. Thus, additional hours mean an increase in production, because every increase in output means a change in the hours worked, which unfortunately is off the record and not subject tax by the current economic and production policy.

Income security and insurance – income security and social insurance system was built to discourage labor unrest and to associate workers to employment. eLancing is threatening the system that provides benefits such as retirement pensions plan, disability, health, and unemployment insurance, and compensation that go with holding a traditional job. eLancers are mostly not eligible and sometimes abuse the system.

Isolation and psychological wellbeing – eLancing threatens our health and also undermines productivity growth due to absence of productive social connections and activities e.g., lack of training and skills development opportunities, lack of workplace public goods, lack of ergonomic worksites, though eLancers have union, but the framework is still fragile and membership is low, and absence of interactions with coworkers or public while commuting as with traditional 9 to 5 jobs.

Benchmark – eLancers, unlike conventional workers are probably too fragmented to agree on output restrictions (Lehdonvirta, 2016), and monitoring virtual coworkers' behaviors is difficult. Thus, the need and awareness for development rarely surface in the eLancing platform.

Unrealistic flexibility (work-family interference) – advocates of flexibilization extol about eLancing ability to liberate individuals to determine their own schedules, while critics enumerated several structural reasons that inhibit eLancers ability to iron out ideal schedules e.g., ability to triumphantly coordinate their schedules relative to other social practices, and their understanding of time matters (Malone, 2004; Wajcman, 2015). Because of eLancing, leisure becomes work, work becomes leisure, “socialization turns costly, and people price every interaction according to market value. Jobs become something that you constantly-and feverishly- seek with very little regularity or certainty” (Lobel, 2017).

Competition, entry barriers, “race to the bottom” – In every sector, barriers of entry, competition intensity and equal employment opportunity matters. An ideal industry should have sufficiently low barriers to allow poor and uneducated people to participate. Nevertheless, if the barriers are too low, competition may lead to a “race to the bottom”, which in the worst-case results in wages falling to a level that no longer contribute to economic development. eLancers who operate in eLancing platforms are subject to intense global competition, which results to low income. For instance, a task that an average American eLancer would execute for \$100 is often executed by eLancers from other regions (i.e., Asia, Africa and Eastern Europe) for only \$30.

FUTURE RESEARCH DIRECTIONS

The importance of e-skills has been cited in previous scholarly (i.e., Gareis et al., 2014). eLancing is still at its nascent stage which comes with several challenges that encompass social, cultural and economic problems. For instance, Stewart and Stanford (2017) stated that several uncertainties and complexities surrounds eLancing work scope, work regulations and legal solutions. This chapter also raises important issues ranging from eLancers insurance, intense competition that results to lower wages, income taxes, psychological distress and the absence of vibrant and clear economic policies to guide the implementation of eLancing work arrangements. eLancing challenges requires urgent attention from researchers because they are pressing issues that need practical solutions. These solutions will contribute to practical usage of eLancing platforms and management theory. Future researchers and policy makers can consider the applicability of several eLancing opportunities into their macro-economic plans.

CONCLUSION

Digitalization and AI technologies have fueled a new wave of work arrangements, in which organizations utilize digital platforms to access national and international talents that would otherwise be inaccessible on demand. On the other edge, “digital economy” of online services has given rise to new kinds

of entrepreneurship and earning opportunities, the eLancing. This borderless, no limit and multi-scope work arrangement is transforming work, work relationship, organizational structure and even business models across the globe. However, milking the benefits in full-scale requires sophisticated skills and technical know-how that is outside the reach of less affluent countries, poor and uneducated people. HR scholars to date have paid comparatively little attention to the eLancing platform. This has created a need to refine and extend management theory beyond full-time traditional employment requires acknowledging the heterogeneity of eLancing activities. The importance of e-skills as part of the economic reforms and policy to prepare future generation for the future work has been cited several times. Additionally, several reforms packages have been proposed and debated. These reforms have been implemented in the European Union. Other countries are encouraged to initiate and implement plans for e-skills developments. eLancing entails several uncertainties about the scope, employment regulations, standards, and remedies. Notwithstanding, policymakers are encouraged to revise the framework governing online labor and/or eLancing. By weighing the pros and cons of eLancing enumerated in this chapter, policy makers can harvest fruitful insights on how to address pressing macro-economic issues that can abate unaccounted transactions, underestimation of employment rate, other economic indicators and labor unrest. Policy makers are encouraged to redefine or expand the definitions of 'employment, create a new category of workers e.g., eLancers, define and distinguish the rights of eLancers from conventional employees e.g., social and health insurance, pension and retirement plan. Subsequently, there is a need to reappraise and review the concept 'employer' e.g., income taxation in the virtual agora. Doing this might define new rights and protections for (i.e., eLancers and client organization) and provides a guide for theory development.

INTRODUCTION

The advancement of the Internet has transformed the way people conduct businesses all over the world. Customers nowadays are equipped with smart mobile devices that can access information about products and services over the Internet easily. Similarly, firms can reach their customers directly through the Internet. Hence, this may cut intermediaries and potentially offer their customers cheaper prices. At the same time, they can engage their customers interactively through the available and specially designed social media. Many new business models have emerged that created disruption to traditional business models, for examples, mobile-based ride-hailing and ride sharing such as Uber, online travel or accommodation agencies such as Travelocity and Trivago, and peer-to-peer rentals such as Airbnb to name a few.

Incorporating the Internet in business is highly influenced by the digitation of business and business transactions, which is divided into three dimensions, (i) product/service digitation, (ii) process digitation and (iii) delivery digitation. Digitations create immense impact in businesses and have created new and innovative business models. For example, both Uber and Airbnb rely on digitation of process as both product/service and delivery cannot be digitized. However, with the digitation of process, they facilitate and manage transactions between supply and demand and create much more efficient business models as compared to the traditional counterparts.

One of the greatest impacts from the digitation of process is the creation of digital marketplaces as it creates immense impact on how supply and demand meet and transact. Digital marketplaces increase effectiveness and efficiency of market functions and significantly lower transactions costs. Essentially, there are three functions of a market, (i) matching buyers and sellers, (ii) facilitating of transactions, and (iii) providing institutional infrastructure (Bakos, 1998). In general, digital marketplaces are firms that offer these market functions digitally in two-sided or multi-sided markets. For examples, Airbnb offers a marketplace accommodation for owners and travelers (two-sided markets) and Uber offers a marketplace for drivers, food outlets and others with their customers (multi-side markets). A two-sided (in general multi-sided) markets is an intermediary or a platform that facilitates or enables collaboration between two sides, producers or sellers and consumers or buyers, to interact and transact (King, 2013; Parker & Van Alstyne, 2005; Rochet & Tirole, 2006). A digital marketplace is a kind of two-sided market that provides digital interactions and transactions to run market functions between both side markets. Literature on two-sided markets has also discussed how a platform creates a price structure which attracts both sides of the market to transact (Armstrong, 2006; Roson, 2005; Rysman, 2009).

DOI: 10.4018/978-1-7998-3473-1.ch091

A platform offers values to both sides to stay in business. Stabell and Fjeldstad (1998) extends Porters' value chain concept (Porter, 1985) into three generic value configurations – value chain, value shop and value network. A platform applies value network as it mediates all sides in multi-sided markets. It provides a networking service or basically providing market functions to facilitate exchange between customers.

The next chapter discusses network externalities, two-sided markets, and value network theories and how these theories can be applied to view digital marketplace firms in setting their expansion strategies. Some digital marketplace business models will also be discussed. Future direction and conclusion will be presented in the last part of this chapter.

BACKGROUND

The advancement of information and communication technology (ICT), especially the Internet, has created a new way of conducting business and business transactions. E-business and e-commerce have been globally adopted and expanding in various sectors.

Globally the size of e-commerce market is growing steadily. For example, retail e-commerce is growing 20.9% yearly. Retail e-commerce was US \$2.3 trillion in 2017 and is expected to reach US \$4.88 trillion in 2021, and one of the most popular activities on the Internet is on-line shopping (Statistica, n.d.).

The Internet has given the opportunity for firms to reach their customers directly, offering direct sales to customers with cheaper prices; interacting with customers and providing them better customer services; providing mass customization and personalization to suit customers' need.

Although customers can find products and services that they need faster through the Internet, with so many firms offering similar products or services, finding the firm that offers suitable products or services directly from the Internet could be time consuming. Similarly, for firms, they may have difficulties to reach their potential customers through the Internet as they cannot easily target the right customers. Digital marketplaces on the Internet help provide the necessary functions for firms or suppliers to meet their customers and facilitate them to transact.

Digital marketplaces are developed along with the development of the Internet. Among early digital marketplaces is eBay. It was founded by Pierre Omidyar in September 1995 and designed to be a digital marketplace to help individuals transact goods and services easily and conveniently (Hasker & Sickles, 2010). There are many digital marketplaces that serve as platforms for business to business (B2B), business to consumer (B2C) and consumer to consumer (C2C) markets. Recently, there are many innovative digital marketplaces that created new markets and grow as global players in a relatively short time. For example, Uber is basically a digital marketplace for the transportation sector and Airbnb is a digital marketplace for the hospitality sector (Oskam & Boswijk, 2016). There are also plenty of digital marketplaces for digital products such as Google Play (Play Store) for Android mobile apps, iTunes for entertainment related products (music, movies, TV shows, etc.), and Craigslist for classified to name a few.

Digital marketplaces also grow locally and regionally, there are many digital marketplaces that concentrate on local/national and regional markets. As they have strong local or regional networks, they can compete with global players. Although local digital marketplaces are accessible globally, expanding a local digital marketplace to global markets is not easy as many factors need to be considered and the local firm needs to have the right internationalization strategy to penetrate global markets.

RELATED THEORIES

There are a number of theories related to digital marketplace, which will be briefly discussed in this section. The first theory is *network externalities*, the second one is *two-side markets*, and the third one is *value network*.

Network Externalities

Utility of an independent product or service such as the utility of air condition is solely based on the product/service. However, there are many cases that the utility of a product/service is also influenced by other products/services or other users (externalities). For example, the utility of computer hardware is definitely influenced by its software and the utility of telephone is clearly influenced by the other telephones connected to the telephone network.

Network externality or network effect (Katz & Shapiro, 1985, 1986, 1992, 1994) is the effect of additional consumers or users of a particular product or service on the utility of existing consumers or users to the same product or service. In other words, the total utility of a product or service for a particular user depends upon the number users of the product or service. Positive externality means additional consumers or users of a product or service increase the utility of the product or service. For example, additional users that join a social network will increase the utility of the social network to existing users or the utility of the social network to a particular user depends upon or a function of total number of users of the network.

Katz and Shapiro (1985, 1986) discuss direct and indirect network externalities, which are discussed further by Clements (2004). Direct network externalities are the direct effect of existing users of a product/service to the utility of purchasing the product/service. For example, the utility of a person purchasing a telephone is directly influenced by number of other telephones connected to the network.

Indirect network externalities are created by complementary products/services. For example, a person who buys a particular car is concerned by number of similar cars sold since services and parts for the car are easily available.

Indirect network externalities can take place in more than one related networks linked by intermediaries. A classic example is a credit card platform such as Visa or MasterCard. The utility of a credit card platform to its customers increases along the increase of total number merchants that accept the credit card issued by the platform. Similarly, the utility of a credit card platform to merchants increases along with the increase of the total number of customers of the platform. Another example is a newspaper that links readers and suppliers or vendors. Clearly the utility suppliers or vendors in buying space for advertisements depend on the number of readers or subscribers of the newspaper.

Intermediated indirect externalities are discussed thoroughly in two-sided networks or two-sided markets literature. In two-sided or multi-sided markets, the network externalities of the one side market depends on the size of the other side (Rochet & Tirole, 2006; Roson, 2005; Rysman, 2009).

Two-Sided Markets

Two-sided or in general multi-sided markets are two or more different but related markets managed by an intermediary or platform in which the growth of one side market is highly influenced by the other side. Two-sided market exhibits indirect externalities (Clements, 2004; Katz & Shapiro, 1985; Roson, 2005). A notable example is credit card platforms mentioned above. The platform manages and facilitates both

markets to interact (and possibly transact). Rochet and Tirole (2004) define two-side markets based on total quantity transacted and the price allocation. A market is a two-side markets if total quantity transacted is not only depends on the per-unit fee collected by the platform, but also depends on the allocation of fees paid by both sides. Rysman (2009) mentioned that the majority of two-side market literatures focus on price allocation. Hence, a marketplace, including a digital marketplace that allow both sides of the market to transact by applying pricing strategy is a two-sided market.

A platform normally provides infrastructure and rules (Eisenmann, Parker, & Alstyne, 2006) that facilitates the two sides to interact and transact. The main task of a platform is to attract both sides to join the platform to interact, and “getting both sides on board”. There are various strategies to fulfill this task but the most important strategy is the pricing strategy. The pricing strategy is basically discussed on how to allocate prices or charges between two sides so that both sides will grow and keep growing because of indirect externalities or cross network effects.

Rochet and Tirole (2004) discuss two charges applied by platforms to both sides, fix membership charge (α) and usage access charge (β), where $\alpha \geq 0$ and $\beta \geq 0$. If S is the seller side and D is the buyer side, pricing strategy is basically the allocation of $S_\alpha + S_\beta$ and $D_\alpha + D_\beta$ is such a way so that both S and D are attracted to transact. In some cases the platform give away the membership charge of one side such as free member charge the buyer ($D_\alpha = 0$) or even both membership and usage charges are free for the buyer side ($D_\alpha + D_\beta = 0$) to attract them to the platform. For example, Adobe (acts as a platform) give away (gratis) Acrobat Reader for documents' readers and charge for a premium license fee for the Acrobat Writer for documents' producers. In fact, a platform apply the lost leader strategy for one side of the market (such as $D_\alpha + D_\beta < 0$), especially during a promotion time, to attract the other side. Price allocation strategy or price structure is an interesting topic discussed by many two-sided markets researches (Armstrong, 2006; King, 2013; Parker & Van Alstyne, 2005; Rochet & Tirole, 2003; Roson, 2005; Rysman, 2009). Eisman et al. (2006) argue that it is very important to get the right price structure and this may imply that a platform subsidizes one side of the market to grow in order to attract the other side and then charge the other side with premium access to subsidize the other side.

Parker and Van Alstyne (2005) thoroughly discuss the price allocation strategy for two-sided markets (they use the term two-sided networks), especially on the issue of giving a subsidy to a side in attracting other side for revenues. They develop a two-sided network model that can determine which side to receive a subsidy or discount. Price allocation strategy is crucial to grow the market, however, there are some other factors that are also important such as the enabler technologies, suitable business models and expansion strategies. For example, e-Bay and Airbnb will not be possible without the Web and Uber will not be possible without the Web, Global Positioning System (GPS), digital map and smartphone.

Value Network

There are several value network concepts discussed in the literature with different approaches (Allee, 2008; Christensen & Raynor, 2013; Peppard & Rylander, 2006; Stabell & Fjeldstad, 1998)

Allee (2008) considers networks are interactive agents that carry specific roles and values geared towards an achievement of a specific task or outcome by converting intangible and tangible assets into negotiable offerings. The key concept of Allee's value network is value conversion where agents engage in intangible and tangible exchanges to achieve economic or social good. A value network is divided into two categories, internal value networks and external-facing value networks. Internal value networks are interactions between or among agents (individuals or work groups) that make up an organization. External-facing value networks are interactions of an organization with its stakeholders.

Christensen (Christensen, 1997; Christensen & Raynor, 2013) defines value network as the collection of related entities in the environment of a business (industry), such as suppliers, channels to market, and ancillary providers that support the business. To compete, any business needs to adapt or conform to its value network.

According to Peppard and Rylander (2006), a value network is a network of connected entities that facilitates complex relationships of different players to deliver services to end customers. Value is created through these relationships. How value is created and its position in a network is described by Network Value Analysis (NVA), which can be used to construct a competitive strategy.

Stabell and Fjeldstad (1998) extends Porters's value chain concept (Porter, 1985) into three generic value configurations – value chain, value shop and value network. A business applies a value network if it mediates customers or clients. Note that the business itself is not a network, but it provides a networking service to facilitate exchange between customers. Thus, the network is the interaction among customers and value network is the service that facilitates the matching among customers. The Stabell and Fjeldstad's value network concept is related to the concept of network externalities. The value creation in a value network is the facilitation and management of exchange among customers and "the value is derived from service, service capacity and service opportunity." (Stabell & Fjeldstad, 1998, p.428)

Figure 1. Value Network Diagram (Courtesy Stabell & Fjeldstad, (1998))

VALUE NETWORK VIEW OF DIGITAL MARKETPLACE

The value network of Stabell & Fjeldstad (1998) integrates the concept of externalities and also absorbs the concept of two-sided market for a platform that manages two-side networks. Stabell & Fjeldstad (1998) extends the Porter's value chain (Porter, 1985) as there are many cases where value are not created by a linear chain of activities. In a value network, value is created when the platform provides services that connect its users/customers to interact and possibly transact. A value network diagram describes the platform activities to create value for its users/customers

Like the Porter's value chain diagram, the value network diagram is divided into primary activities and support activities. The primary activities are composed of overlapping activities: *network promotion and contract management*, *service provisioning*, and *network infrastructure operation*. The support activities are composed of separate activities: *firm infrastructure*, *human resource management*, *technology development*, and *procurement*. Figure 1 depicts the diagram of a general value network.

Support Activities

Firm infrastructure is a set of activities related with running business functions and operations such as general management, accounting, finance, and information systems. Human resource management is a set of activities related to managing human resources such as recruitment, training, and promotion. Technology development is a set of activities related to network development and service development. Procurement is a set of activities related to purchasing network infrastructure and service development.

Primary Activities

Network promotion and contract management is a set of activities that attract customers to join the network, setting the joining requirements, initialization, management and termination of contracts. Service provisioning is a set of activities related to initiating, operating and terminating services. Infrastructure operation is a set of activities for operating and maintaining both physical and information infrastructure.

Services offered and the networks itself create values. However, these values can be boosted further through network effects or positive network externalities. According to Katz and Shapiro (1985) value of a service is a function of positive network externalities. This means adding a node (such as a customer) to the network will affect the value of the service to other nodes.

Digital marketplaces are platforms in which value is created through value network. The value network diagram (Figure 1) is very useful to help a platform owner crafting a competitive strategy and business expansion on the chosen business model.

BUSINESS MODELS

Many digital marketplaces grow with innovative business models based of platforms of two-sided or multi-sided markets or networks. Basically a business model is a framework or architecture on how a business is organized and financed to create, deliver and capture value. Teece (2010) defines business model as a concept that describe the mechanism of a firm creates and deliver value to customers and making profits through the payment of the value. Hence, a business model has to outline the detail on

how to create value and how customers receive the value as well as making profits from the revenue generated by the value.

Teece (2010) provides elements of business model design which create value for customers. The value can be the fulfilling needs of customers or offer solutions to their problems. As such, customers do not hesitate to pay the value on the price offered. The firm captures the value that it creates and delivers through converting payments from customers into profits. According to Teece (2010) business model design has the following elements: 1) select technologies and features to be embedded in products/services, 2) determine customers' benefits from consuming products/services, 3) identify the segment of the target market, 4) confirming the availability of revenue streams, and 5) design mechanism to capture value.

Osterwalder and Pigneur (2010) identify 9 building blocks of business model, which are *customer segments*, *value propositions*, *channels*, *customer relationship*, *revenue streams*, *key resources*, *key activities*, *key partnership*, and *cost structure*. These 9 building blocks are arranged to form the Business Model Canvas (BMC) that can be used to describe, analyze and generate business model. Figure 2 is the structure of BMC.

Figure 2. Business Model Canvas (Osterwalder & Pigneur, 2010)

Key Partners	Key Activities	Value Propositions	Customer Relationships	Customer Segments
	Key Resources		Channels	
Cost Structure			Revenue Streams	

Based on Teece's definition of business model, also the building block of BMC, Täuscher & Laudien (2017) classify digital marketplaces into six clusters namely, *efficient product transactions*, *digital product community*, *Product aficionados*, *on-demand offline services*, *online services*, and *peer-to-peer offline services*.

Efficient product transactions are marketplaces that offer efficient transactions on physical products between individuals or businesses (C2C and B2B). The majority of the platforms use commissions to generate revenue, although some of them also use subscriptions to generate revenue. *Digital product community* facilitates transaction on digital products, although some products may not necessarily digital. Most transactions in the community are between individuals (C2C), although there are also B2C transactions. A platform in this category generates revenue through commissions. *Product aficionados* are marketplaces typical physical products such as art and handmade products and build communities

Table 1. Six clusters of digital marketplace models (taken from Täuscher & Laudien (2017))

Business model type	Platform type	Platform participants	Value proposition	Transaction type & good	Revenue model	Example
Efficient product transactions	Web-based platform	C2C, B2B	Large product variety	Physical products	Commission fee, subscription fee; mostly supply side	Beepi (eBay for used cars)
Digital product community	Web-based platform	C2C	Being part of a primary non-commercial community	Digital products; physical products	Commission fee; supply side, demand side	Sellfy (connecting 'neighbors' to share durable goods with each other)
Product aficionados	Web-based & mobile platform	B2C, C2C	Exchanging knowledge about niche products with community of like-minded people	Physical products	Commission fee; supply side	HobbyDB (Knowledge database and transaction platform for collectibles)
On-demand offline services	Web-based & mobile platform	B2C	Large service variety in a novel form	Offline services	Commission fee, subscription fee; mostly supply side	StyleSeat (connecting beauty salons & consumers)
Online services	Web-based platform	C2C, B2C	Novel online services with social networking character	Online services	Commission fee, subscription fee; mostly supply side	iTalki (connecting language learners with teachers for 1-on-1 online lessons)
Peer-to-peer offline services	Web-based & mobile platform	C2C	Novel services with community feeling within & outside digital platform	Offline services	Commission fee (demand & supply side), subscription fee (third parties)	Airbnb (connecting people to list, discover, and book private accommodations)

to share passion on these products. Most of transactions are within B2C, although there are also many C2C transactions. Revenues are generated through commissions and/or subscriptions of the seller side. *On-demand offline services* are marketplaces that facilitate online transactions of services between providers and their users. Services are carried out physically such as car rides or ride hailing, delivery services and shipping. Revenues are generated through commissions (most commission taken from the seller or provider side). *Online services* marketplaces are similar to the previous ones, however, all services are carried out digitally via the Internet and revenue are normally generated through commissions. *Peer-to-peer offline services* provide platforms for individuals that can offer services physically to those individuals who need them. In general, a platform in this category provides efficient way for individuals to share their physical resources, time or skills. Furthermore, most platforms in this category generate revenue through commissions. Table 1 summarize feature of the six clusters of digital marketplaces identified by Täuscher & Laudien (2017).

FUTURE RESEARCH DIRECTIONS

We are witnessing a growing number of companies adopting the digital marketplace model with various expansion strategies. Interestingly, the number of new companies that are adopting the digital marketplace,

successfully grow their business in a relatively short time and create disruption to the established players such as Airbnb in the accommodation industries or Uber in the transportation industry. Research on digital marketplace or digital platform is still in its infancy although a number of publications are growing recently. Some future research directions should include digital marketplace economy, this include impact of digital marketplaces in the national economy and the society; digital marketplace ecosystem this including studies on business ecosystem of digital marketplace and competition within an ecosystem and among similar ecosystems; studies on impact of digital marketplaces on the traditional business will be interesting as well; There are also an increasing number of studies on value co-creation. Focusing studies on value creation and value co-creation on digital marketplace is another good study to pursue.

CONCLUSION

A digital marketplace is a virtual platform that mediates two or more markets (two-sided or multi-sided markets) and creates value by governing efficient interactions between consumers from different markets. The main business strategy of most marketplaces is to expand markets they govern through a network effect to boost the value of their platforms. To do this, a marketplace is not only needed to create an effective pricing strategy to its customers, it also needs to increase the value of its mediation power and to make sure the support from its stakeholders.

Many innovative business models have been crafted within digital marketplace realm. These innovative business models have made the associated marketplaces grow so fast, much faster than traditional companies since all business processes and interactions are digitized, although services or products are not necessarily digital services or products.

KEY TERMS AND DEFINITIONS

Business Model: A concept that describes the mechanism of a firm that creates and delivers value to customers and making profits through the payment of the value.

Digital Marketplace: A platform that governs interactions between two or more different markets and creates different values for different market and captures those values mainly through subscription and/or commissions.

Network Externalities: Network externality or network effect is the effect of additional consumers or users of a particular product or service on the utility of existing consumers or users to the same product or service.

Two-Sided Markets: Two-sided or in general multi-sided markets are two or more different but related markets managed by an intermediary or platform in which the growth of one side market is highly influenced by the other side.

Value Network: A value configuration in which value is created through providing connection or mediating interactions with consumers.

Crowdsourcing Maturity and Its Application in Public Organization Management

Regina Anna Lenart-Gansiniec

Jagiellonian University, Poland

INTRODUCTION

Crowdsourcing is an important variable in the research on public organizations. Crowdsourcing is important for generating information, improving communication between employees of a public organization and citizens (Brabham, 2015), engaging citizens in creating services (Noveck, 2009), solving public problems (Mergel and Desouza, 2013), shaping policy (Prpić et al., 2015), and improving public services (Nam, 2012). In addition, crowdsourcing increases the capacity of citizens' participation in public life, the sense of having a chance to make changes in their immediate environment (Seltzer and Mahmoudi, 2012). Crowdsourcing is part of contemporary public organization management trends (Lenart-Gansiniec, 2019; Nam, 2012). It is considered part of the New Governance, a new method of civic empowerment. It is also compared with e-government and Digital Era Government, open government, and instruments of social participation (Dutil, 2015). However, the implementation of crowdsourcing by public organizations alone does not contribute to achieving the assumed benefits, it is important to manage it (Blohm et al., 2018). The basis is improvement of specific skills and abilities by the organization in the context of crowdsourcing and its readiness to implement crowdsourcing, thus obtaining crowdsourcing maturity (Birch and Heffernan, 2014).

In the literature it is suggested that starting to implement and use crowdsourcing by the organizations should be preceded by significant organizational changes related to the processes, infrastructure, and organizational culture – it is only then when the organizations may include crowdsourcing in their strategies and consider its strategic application. The evaluation of crowdsourcing maturity may constitute a set of principal requirements and framework guidelines for a given process. The existing empirical achievements quite unequivocally prove the importance of crowdsourcing for the functionality, effectiveness, and efficiency of public organizations; however, it does not answer elementary questions, what crowdsourcing maturity of public organizations really is and what is the level of this maturity in public organizations, in particular in municipal offices. The search for answers to these questions seems to be justified for two reasons.

The aim of this article is to identify the level of crowdsourcing maturity of municipal offices in Poland.

BACKGROUND

Crowdsourcing

There is no agreement in the literature on the way crowdsourcing should be defined, although a significant number of researchers refer to the findings of Howe (2006). In this perspective, crowdsourcing means “the act of a company or institution taking a function once performed by employees and outsourcing it to an undefined (and general large) network of people in the form of an open call. Postulates appear in the literature that in order to conduct research on crowdsourcing, those of its areas should be taken into account (Zhao and Zhu, 2014) which are related to crowdsourcing components. In the crowdsourcing approach adopted, three areas of crowdsourcing have been specified, i.e. organizational, individual, and technological (Table 1). The adequacy of such a specification of crowdsourcing areas is also confirmed by Rouse’s (2010) findings. This fits in with the researchers’ deliberations started in 2018 on the topic of effective crowdsourcing management, taking into account precisely the intra-organizational perspective (Blohm et al., 2018).

As part of the organizational scope of crowdsourcing, the activities undertaken by the organization-initiator are important. In particular, this area allows to answer the question whether the problem addressed to the virtual communities by the organization has been properly assigned to a specific task. In addition, within this area crowdsourcing processes, intellectual property protection aspects, crowdsourcing coordination mechanisms, methods of acquiring, motivating virtual communities and evaluation of ideas sent by this community are indicated (Schenk and Guittard, 2011). The individual area focuses on the importance of employees in crowdsourcing endeavors. It is emphasized here that an appropriate motivation of employees, perceiving the benefits of crowdsourcing by them can cause that new solutions and ideas obtained from virtual communities will be adopted, disseminated, assimilated, and used to propose improvements in their workplace or for the entire division/department and building own reputation. The next area, technological, concentrates on the technical aspects of crowdsourcing. It allows for indicating software components, technical functions, important for the success of a crowdsourcing initiative, including: interface, authentication of the users, tracking the history of their posts, payment mechanisms, quality and workflow control and adaptation to the organization’s contextual, relational, and situational needs (Erickson et al., 2012).

Crowdsourcing Maturity

On the basis of management sciences, maturity is perceived as: the degree of the organization preparation for the implementation of specific tasks in a comprehensive manner and the achievement of its set goals, achieving a state of full development including the possibility of achieving excellence, the resultant of the maturity of business processes resulting from the organization’s activity and the maturity of the teams implementing these processes, as well as the normative, postulated procedure. Such approach to maturity is a set of basic and specific requirements or framework guidelines - which allows for diagnosing the current state of maturity and determine the target one. Among the few scientific studies one can find the statement that crowdsourcing maturity determines the actions that the organization should perform to achieve the desired crowdsourcing state. According to Birch and Heffernan (2014), crowdsourcing maturity is a certain ability of organizations and processes to achieve the assumed benefits of crowdsourcing (Birch and Heffernan, 2014). On the other hand, Boughzala et al. (2014) state that crowdsourcing

maturity consists of activities, processes, and their management that allow for improving crowdsourcing initiatives, and more specifically transiting from the initial state to an advanced state.

The manifestation of the organization's maturity are the specific features, which is associated with the skills that demonstrate the organization's readiness to implement certain tasks. The more the organization meets the requirements in more areas, the more it deserves to be called crowdsourcing mature. If, therefore, we assume that the maturity is the competences, skills, level, or degree of advancement of a chosen area of the organization, it can be recognized that crowdsourcing maturity is the degree of the organization's preparation for crowdsourcing implementation. This approach emphasizes the need for organizational changes in terms of the processes, infrastructure, and organizational culture (Howard et al., 2012), which increases efficiency and readiness to perform tasks, customer satisfaction, reduces costs, and contributes to building the organization's competitive advantage (Fisher, 2004). This means, therefore, that mature organizations carry out specific activities systematically, regularly, in a planned and conscious manner and are oriented towards continuous development, improvement of competences, and learning. An immature organization is one that performs specific actions chaotically, spontaneously, often only on a one-off basis or does not perform them at all. Crowdsourcing maturity models are used to identify the desired and current level, but also to evaluate the activities performed as part of the crowdsourcing framework. In the literature on crowdsourcing, only few models of maturity can be identified. They are usually original and have not been verified by other researchers. For example, the Crowdsourcing Ideation Maturity Assessment Model (CIMAM) by Boughzala et al. (2014) is intended to be so universal that it can be used to assess various types of crowdsourcing initiatives. According to the assumptions adopted by the authors, it may be helpful when choosing a crowdsourcing platform provider and selecting and evaluating ideas developed by virtual communities.

Other researchers, Birch, and Heffernan reviewed ten models of crowdsourcing maturity assessment in clinical trials. They considered that two of them, i.e. the Project Management Maturity Model (ProMMM) by Hillson (2003) and the National Infrastructure Maturity Model (NIMM) by van Dyk et al. (2012) - are so universal that they can be useful to assess crowdsourcing maturity in organizations. The ProMMM model focuses on the assessment of the skills of the management staff involved in crowdsourcing, while the NIMM on the assessment of the maturity of clinical trials using crowdsourcing. As indicated, both models discussed above can be used to assess crowdsourcing maturity in activities related to gathering of clinical data, patient reporting, treatment, and control of clinical signs and symptoms, and thus all practices involving medicine. Their verification has not been carried out in sectors other than medical. It is therefore difficult to consider these models as universal and transfer them to other organizations. The General Crowdsourcing Maturity Model (G-CrMM) by Durango Yepes and Gil Vera is based on the approach proposed in the National Infrastructure Maturity Model (NIMM). The authors stated that understanding the overall development of crowdsourcing required a strategic and systematic view of crowdsourcing. However, this model has not been verified empirically. The presented crowdsourcing maturity models are typically developed for business organizations and do not take into account the specificity of the public organization. In literature, however, it is difficult to find models of crowdsourcing maturity dedicated to public organizations. In one case, Lee and Kwak proposed an open government maturity model. The authors distinguished five levels oriented on the use of a website, the presence of the organization in the social media and the use of other technologies to communicate with residents (Lee and Kwak, 2014). However, this model is not useful for assessing crowdsourcing maturity.

RESEARCH METHODOLOGY

The research began in January 2018 and ended in June 2018. In the process of collecting the questionnaire survey data, the Computer Assisted Web Interview technique was used, which implies conducting surveys using survey questionnaires made available electronically. The choice of this technique was dictated by the possibility for the respondents to maintain their anonymity, the desire to eliminate the adverse effects associated with the presence of the researcher and the possible impact on the answers provided. Moreover, this technique can be used despite spatial limitations as it allows for completing the survey in any place and time convenient for the respondent. A simple percentage measure were used to identify the level of crowdsourcing maturity of municipal offices in Poland.

A total of 501 municipal offices participated in the survey, including 205 using crowdsourcing. In order to identify what percentage of municipal offices uses crowdsourcing and whether crowdsourcing maturity actually contributes to the municipal offices' organizational learning, compared to those that do not use it - a filtering question was used in the survey questionnaire, which enabled the separation of municipal offices that use crowdsourcing from those that do not. Generally, the municipal offices participating in the survey mainly pertain to cities of up to 20 thousand inhabitants (55.49%), employing between 50 and 99 people (45.51%%). The respondents were women (59.68%) in the age group of 41-50, (33.73%), employed in managerial positions (79.44%%), with seniority of over 10 years (68.26%%), with higher education (97.00%).

Taking into account the lack of tools for measuring public organizations' crowdsourcing maturity found objectively, an original survey questionnaire has been proposed. It has been assumed that the development of a crowdsourcing maturity assessment tool may be a diagnostic instrument to identify areas that the organization should improve. On the other hand, the measurement of crowdsourcing maturity will allow to observe the progress and the level of advancement of a given crowdsourcing initiative, and further to discipline, organize, and systematize the crowdsourcing used and set directions for action in improving management. The proposed tool in the 5-point Likert scale (where 1 –means a definite lack, and 5 - a strong relationship) contains 24 questions grouped into three areas of crowdsourcing maturity: organizational, individual, and technological. The general basis for the creation of a tool for measuring crowdsourcing maturity of municipal offices the methodology for measuring the maturity by Yepes and Vera (2014) has been adopted in the study. The choice of methodology was guided by important premises, i.a.: simplicity and the possibility of quantitative analysis, functionality, diversity of perception, and the desire to maintain continuity. It should be noted that the primary purpose of the crowdsourcing maturity tool is to provide clues that are logically related to each other and serve a specific purpose - however, it should not simplify the reality (de Bruin et al., 2005).

In order to better understand crowdsourcing maturity with division into three areas, an attempt was made to visualize it in the form of a crowdsourcing maturity evaluation key. The proposed key, in reference to the findings in sub-chapter 2.2, consists of three areas: organizational, individual, and technological. The basic simplification is the adoption that each of these areas affects the growth of crowdsourcing maturity (each has approximately a 33.33% share in it). The adoption of 33.33% of the total share in each of the areas results from the fact that in the literature, as far as it is known to the authoress, the significance of a given area is not indicated. Hence, individual areas complement each other and they create a full and comprehensive image of crowdsourcing maturity. Achieving crowdsourcing maturity is linked to the improvement of specific skills, characteristics, and abilities in a given area (defined as parameters), which is important for the level of maturity (Table 1).

Table 1. Crowdsourcing maturity evaluation ley

Areas	Parameters	Levels					Total share in an area (in %)
		1	2	3	4	5	
Organizational	Procedures on acquiring opinions from residents	0.83	1.66	2.49	3.32	4.15	33.33
	Ordinance implementing crowdsourcing	0.83	1.66	2.49	3.32	4.15	
	Crowdsourcing initiative coordinator	0.83	1.66	2.49	3.32	4.15	
	Crowdsourcing initiative target group	0.83	1.66	2.49	3.32	4.15

Municipal office crowdsourcing maturity in the technological area (in %)							
0–20 21–40 41–60 61–80 81–100	Very low level of crowdsourcing maturity in the technological area (initial) Low level of crowdsourcing maturity in the technological area (repeatable) Moderate level of crowdsourcing maturity in the technological area (standard) High level of crowdsourcing maturity in the technological area (managed) Very high level of crowdsourcing maturity in the technological area (model)						

Source: own elaboration.

In order to determine the level of a given area, one should diagnose a set of parameters characterizing it. Therefore, it has been assumed that the more parameters the municipal office implements, the more it deserves to be called a crowdsourcing mature office. In this approach, maturity is reduced to the degree of complexity and quality of the parameters implemented in a given crowdsourcing area. The total level of all parameters of a given area determines its percentage share in the crowdsourcing maturity generation processes. Whereas, the level of maturity of individual parameters determines the level of maturity of a given area and translates into the level of crowdsourcing maturity. In particular areas, the parameters complement each other, hence the share in the generation of crowdsourcing maturity attributed to them can be added up - which reflects the share of a given area in the perceived crowdsourcing maturity of a given office. In total, 24 such parameters were identified in the model: in the organizational area - 8 parameters in the individual area - 6 parameters in the individual area and 10 in the technological area. For each of the three areas, dedicated wording was prepared. Their content was formulated on the basis of a literature review. Taking into account these assumptions, in order to qualify a given office to a given level of crowdsourcing maturity, a specific evaluation key for particular areas has been proposed.

RESULTS

The conducted research revealed that the municipal offices studied use 63.45% of their capabilities, which means a high level of crowdsourcing maturity. With reference to the organizational area of crowdsourcing maturity, the offices studied use 65.13% of their capabilities, 57.95% in the individual area, and 65.40% of capabilities in technology. A detailed analysis of the responses obtained allows for noticing that in the organizational area of crowdsourcing, the procedures for acquiring opinions from residents, the appointment of a crowdsourcing coordinator and the determination of an initiative's target group were rated the most, while the methods of rewarding the virtual community were rated the lowest. In the individual area of crowdsourcing maturity, the employees' commitment to new projects was rated the highest, further informing employees about the crowdsourcing initiative and precise rules for appointing people responsible for coordinating crowdsourcing. The lowest notes were obtained by the component related to conducting crowdsourcing training. In the technological area of crowdsourcing maturity, the functionality of the platform associated with the possibility of reporting problems troubling the virtual community was rated the highest, while the lowest rate was obtained by the possibility of evaluating ideas reported by the Internet users.

First, five municipal offices (2.44%) were included in the first level of crowdsourcing maturity. However, 10.24% (21 municipal offices studied) are characterized by low maturity, moderate - 25.85% of the units studied (53 offices studied), high maturity - 44.40% of offices (91 offices studied), and finally very high crowdsourcing maturity was attained by 17.07% units (35 offices studied). Analyzing crowdsourcing maturity of municipal offices characterized by low crowdsourcing maturity (2.44% of the studied offices declaring the use of crowdsourcing) using control sheets, it should be noted that they use 20% of their abilities in the area of crowdsourcing maturity, including: 20% in the organizational area, 20% in the individual area, and 20% in the technological area. It follows that in these offices no procedures have been developed to obtain opinions from residents - as indicated by 100% of the surveyed municipal offices. The same number of respondents recognized that there was no ordinance implementing crowdsourcing in their office. There were also no crowdsourcing initiative coordinators (100%), and the target group of the crowdsourcing initiative (100%), methods of engagement (100%), motivating Internet users (100%), and rewarding them (100%) had not been determined. In the case of

defining tasks that were to be transferred to virtual communities, 100% of the municipal offices studied that are at the first level of crowdsourcing maturity do not do that. Employees in offices located at the first level, according to the respondents, do not know about the crowdsourcing initiative used in their unit (100%), they did not participate in crowdsourcing training (100%), they are not encouraged to use knowledge from crowdsourcing and are reluctant to engage in new projects (100%). The offices had not developed any rules for assessing the employees' use of knowledge coming from crowdsourcing (100%) and rules for appointing people to coordinate this initiative (100%). The crowdsourcing platform owned by the investigated offices at the first level tends to have regulations (80%), which are generally available (80%). The platform rather includes criteria for evaluating ideas sent by members of the virtual community (80%). The owned platform a tool enabling the office to communicate with the residents (80%) and the residents with the office (80%). In addition, it has the following functionalities: the ability to comment the posts of other members of the virtual community (80%), vote for the best ideas, in their opinion (80%), the opportunity to report problems that trouble them (80%), collect and store the knowledge resources acquired in this way (80%). The platform also contains information pertaining to the implementation of the winning ideas.

Second, 21 municipal offices studied were qualified to the second level (10.24%). Research conducted in these offices indicates that they use 28.33% of their capabilities in the field of crowdsourcing maturity, including: 26.78% in the organizational area, 32.38% in the individual area, and 27.14% in the technological area. Over 33.3% of the examined municipal offices positioned at the second level, stated that they rather had procedures for obtaining opinions from residents (14.3% of respondents declared a lack of such procedures). As regards the implementation of crowdsourcing, 71.4% of the respondents believe that they do not have one. In the overwhelming majority of offices positioned at the second level, no crowdsourcing initiative coordinator had been appointed (61.9%), no target group of the crowdsourcing initiative (61.9%), methods of engaging the virtual community (85.7%), motivating Internet users (71.4%), and methods of rewarding them (71.4%) had been determined. In turn, 57.1% of the offices studied had not defined tasks that were to be transferred to the virtual community. Offices, at the second level of crowdsourcing maturity, had not provided their employees with information about the crowdsourcing initiative (61.9%), they had not provided training in this area (100%), and they had not encouraged them to use knowledge coming from crowdsourcing (76.2%). However, in 42.9% of the municipal offices studied, the employees are willingly engaging in new projects (19% declare that "definitely yes"). On the other hand, 76.2% of the municipal offices studied, which are at the second level, declare that they do not have the rules of employees' assessment in terms of their use of knowledge coming from crowdsourcing. Whereas, 100% of the respondents point to the lack of rules for appointing people to implement crowdsourcing initiatives. The crowdsourcing platform owned by the studied second level offices definitely does not have any regulations (100%), and which are not generally available (90.5%). The platform does not rather include criteria for evaluating ideas sent by members of the virtual community (90.5%). The platform is not a tool for the office that allows for communicating with the residents (71.4%) and the residents with the office (61.9%). On top of that, the platform does not have the following functionalities: the ability to comment the posts made by other members of the virtual community (81%), vote for the best ideas in their opinion (71.4%), report problems that trouble them (57.1%), collect and store knowledge resources (61.9%). The platform does not provide information on the implementation of the winning ideas (71.4%).

Third, at the third level there are 53 municipal offices studied (25.85%). Research in these offices indicates that they use 54.53% of their capabilities in the area of crowdsourcing maturity, including 56.88% in the organizational area, 46.48% in the individual area, and 57.47% in the technological area.

The research results indicate that 45.3% of them, in relation to having procedures for obtaining opinions from the residents, answered: “neither yes, nor no”. The same indications were obtained by the parameter connected with crowdsourcing implementation - 41.5% answered “neither yes, nor no”. In turn, 39.6% of the offices studied gave the answer: “neither yes, nor no” connected with appointing a crowdsourcing initiative coordinator. However, 20.8% have already done so. The offices studied neutrally assessed the fact of determining the target group of the crowdsourcing initiative (49.1%), methods of engaging the virtual community (62.3%), motivating Internet users (47.2%), and rewarding them (49.1%). On the other hand, only 3.8% of the municipal offices studied defined tasks that were to be transferred to the virtual community. Offices at the third level neutrally assessed the fact that employees had knowledge about crowdsourcing (41.5%) used. As regards conducting training for employees in the area of crowdsourcing, 49.1% of respondents felt that this was not the case. The offices studied do not encourage the employees to use the knowledge acquired as part of crowdsourcing (37.7%) - 41.5% answered “neither yes, nor no”. It was declared that the employees are rather willing to engage in new projects (30.2%). In addition, these offices do not have well-developed rules for assessing the employees’ use of knowledge acquired from crowdsourcing (47.2%). Only 9.4% have developed rules for appointing people to implement a crowdsourcing initiative - while 35.8% gave a neutral answer, and 34% said that there were rather no such rules in their offices. The fact of having the crowdsourcing platform regulations by the third level offices studied was assessed at the neutral level (43.4%), while 18.9% confirms the definite fact of having them. On the other hand, disclosure of the regulations was assessed neutrally - 37.7% answered “neither yes, nor no” (18.9% definitely confirms this fact). The platform definitely does not include criteria for assessing the ideas sent by the virtual community members (35.8%). The possessed platform is rather not a tool for offices that allows for communicating with the residents (30.2%) and the residents with the office (30.2%). In addition, the platform does not provide the possibility of commenting on the posts of other virtual community members (24.5%), voting for the best ideas, in their opinion (41.5%). However, it allows for reporting problems that trouble them (30.2%). As to the collection and storage of the acquired knowledge resources, the following answers were obtained: 28.3% recognize that the platform does not allow it, while 24.5% state that it rather allows it (80%). Usually, the platform does not contain information about the implementation of winning ideas (45.3%).

Fourth, at the fourth level there are 91 municipal offices studied (44.40%). Research in these offices indicated that they use 69.62% of their capabilities in the area of crowdsourcing maturity, including: 71.62% in the organizational area, 63.5% in the individual area, and 71.67% in the technological area. These offices have procedures for obtaining opinions from residents (46.2% of the municipal offices studied declare this fact). The respondents indicated that they rather have an ordinance implementing crowdsourcing (31.9%). On the other hand, 42.9% assess this parameter neutrally. In 49.5% of the municipal offices studied, the crowdsourcing initiative coordinator had been appointed, while 5.5% had not done so. The target group of the crowdsourcing initiative (61.5%), the ways of engaging the virtual community (49.5%) had rather been defined, while this parameter was neutrally assessed by 42.9% of the offices studied. The parameter regarding the methods of motivating Internet users (56%) and their rewarding (50.5%) was also neutrally assessed. In turn, 46.2% of the municipal offices studied had rather defined tasks to be transferred to the virtual community. At the fourth level, 44% of the studied municipal offices found that the employees rather had knowledge about the crowdsourcing initiative. As for conducting training for employees in the area of crowdsourcing, 40.7% of the respondents considered that this had not been the case, and 20.9% stated that it had rather been conducted. Offices at this level usually do not encourage their employees to use knowledge obtained from crowdsourcing (34.1%), while 42.9% answered: “neither yes, nor no.” In the offices at this level, the employees are willing to engage in

new projects (53.8%). The respondents neutrally assessed the parameter related to possessing developed rules for assessing the employees' use of knowledge acquired from crowdsourcing (40.7%). Only 4.4% have developed rules for appointing people to implement a crowdsourcing initiative, while 54.9% gave a neutral answer (27.5% stated rather yes). The crowdsourcing platform owned by the studied offices at the fourth level rather has regulations (39.6%). However, its availability was assessed neutrally - 41.8% stated "neither yes, nor no" (16.5% definitely confirms this, while 35.2% considers rather yes). The platform rather includes criteria for evaluating ideas sent by members of the virtual community (31.9%). The platform is usually a tool for the office enabling communicating with the residents (45.1%) and the residents with the office (49.5%). The possibility of commenting on the posts made by other members of the virtual community was assessed as neutral (34.1%). The offices studied declare that their platform allows for voting for the best ideas, in their opinion (44%), reporting problems that trouble them (44%), gathering and storing the acquired knowledge resources (50.5%). The platform also includes information on the implementation of the winning ideas (53.9%).

Fifth, on the fifth level there are 35 city offices using crowdsourcing (17.07%). Research in these offices indicates that they use 88.19% of their capabilities in the field of crowdsourcing maturity, including: 90.21% in the organizational area, 81.5% in the individual area, and 90.57% in the technology area. Offices positioned at this level have procedures for obtaining opinions from residents (74.3%). When assessing the existence of the crowdsourcing implementing ordinance, 45.7% stated that the office had rather had one, while 42.9% of the respondents considered that such an ordinance had definitely existed. In 68.6% of the studied offices positioned at level five, the crowdsourcing initiative coordinator had been appointed, while 65.7% had definitely defined the target group of crowdsourcing and the ways of engaging participants (54.3% - rather, while 45.7% - definitely). In the case of determining the methods of motivating Internet users, 43% of respondents felt that they had rather been determined. On the other hand, 42.9% of the municipal offices studied claim that the methods of rewarding the virtual community have been developed. The fact of determining the tasks to be transferred to the virtual community was assessed in a similar way. At the fifth level, 51.4% of the studied offices declared that the employees had knowledge about the crowdsourcing initiative, while this standpoint was definitely accepted by 40% of the respondents. Offices positioned at this level declare that training on crowdsourcing for the employees was definitely conducted (28.6%), while 22.9% stated that it had rather not been conducted. Offices at this level rather encourage their employees to use knowledge acquired as part of crowdsourcing (51.4%), while 37.1% answered "definitely yes".

In the offices studied, the employees are usually willing to engage in new projects (60%). Additionally, these offices have rather developed rules for assessing the employees' use of knowledge acquired from crowdsourcing (42.9%). In the case of a parameter connected with the existence in the office of rules for appointing people to implement a crowdsourcing initiative - this fact is confirmed by 40% of offices positioned at the fifth level, while 54.3% considered that such rules had rather been established. The crowdsourcing platform owned by the examined offices positioned at the fifth level definitely has regulations (54.3%), which are generally available (71.4%). On the platform, there the criteria for evaluating ideas sent by members of the virtual community are rather present (48.6%). The owned platform is for the office a tool enabling communication with the residents (65.7%) and the residents with the office (65.7%). The platform's functionalities include: the ability to comment on the posts made by other members of the virtual community (40%), voting for the best ideas, in their opinion (85.7%), the opportunity to report problems that trouble them (82.9%), gathering and storing the acquired knowledge resources (77.1%). The platform also includes information on the implementation of the winning ideas (71.4%).

DISCUSSION

8

Our research focused on identifying the level of crowdsourcing maturity of municipal offices in Poland. Although there have been no previous studies focusing on crowdsourcing maturity of municipal offices, there are some empirical results with actions aiming at gaining benefits from crowdsourcing and its management, as well as key success factors. Taking into account the theoretical foundations applied, our research supports the studies on crowdsourcing maturity conducted by Durango Yepes and Gil Vera. Taking into consideration the previous empirical findings, it is claimed that the results obtained should be perceived as supporting, deepening, and widening the previous ones. This applies, in particular, to the findings related to the managing and designing of crowdsourcing in public organizations (Clark and Logan, 2011; Clark et al., 2019; Noveck, 2009). First, in order to obtain optimal solutions in terms of the amount and diversity of knowledge from crowdsourcing participants, public organizations must develop procedures for obtaining opinions from residents, a document implementing crowdsourcing, plan the coordination of a crowdsourcing initiative, define its target group, the methods to engage, motivate, and reward the virtual community. It is also important to define the tasks addressed to these communities. The quality of the knowledge acquired by the organization is dependent on the level of engagement of a given virtual community member. It is also important to select the right members of the virtual community considering the specificity of the task and to determine the appropriate size and diversity of the said community. On the other hand, an appropriately selected task may contribute to the motivation of the virtual community and encourage it to act and will help achieve the goal set by the office. In particular, the task should be characterized by autonomy, diversity, degree of difficulty, whereby autonomy means the degree to which the task allows for freedom, independence, anonymity, capability to adapt the schedule and procedures to the participants' individual needs, but also the ability to divide tasks into smaller parts. However, diversity is connected with the degree to which a specific task requires from the crowd to use skills and knowledge in its implementation.

Second, the individual area of crowdsourcing maturity is based on the assumptions that before the organization can use crowdsourcing, it must remember the motivation, knowledge, commitment, attitude and behavior of its employees. Implementation of crowdsourcing may be associated with the fear and reluctance felt by the employees. It is not without significance in the individual area to communicate changes, which is connected with conducting training and allowing for ongoing answering the employees' questions - so that they do not recognize crowdsourcing as a threat and do not feel confused. In general, in this area it is important not only to constantly inform the employees about the benefits of crowdsourcing, but also to supervise the use of new knowledge in daily work, which means that all employees should benefit from it in a similar way. For example, Andriole (2010) examined 100 organizations and demonstrated that only 6% of employees used the knowledge acquired from online communities in their work, and 4% to support decision-making processes.

Third, the crowdsourcing maturity level is determined by the parameters in the form of the crowdsourcing platform's functionality, including: the platform's regulations and its general accessibility, the ability to comment and vote. Hosseini et al. (2014) indicate that the crowdsourcing platform should enable interaction with the virtual community, including: the ability to register and log in for individual members of the virtual community, their authentication, declaration of skills and abilities, assigning tasks, sending ideas, coordination, supervision and the said feedback.

Our research shows that the majority of activities within a given crowdsourcing maturity area are undertaken, however the engagement of the employees of the examined offices in new projects and the fact of placing on the crowdsourcing platform information on the implementation of the winning ideas

is of the greatest importance. On the other hand, training for employees in the field of crowdsourcing was rated the lowest.

CONCLUSIONS

The conducted research allowed to deepen the existing knowledge, clarify and verify the theoretical postulates concerning crowdsourcing maturity formulated in the literature. First of all, crowdsourcing maturity is the degree to which the organization's resources in the organizational, individual, and technological areas enable the implementation of crowdsourcing and achieving the assumed benefits arising from it. Second, the conducted research has allowed to develop an original tool for measuring crowdsourcing maturity of a public organization, taking into account the organizational, individual, and technological areas. In order to qualify a municipal office for a given level of crowdsourcing maturity, a sheet for the evaluation of individual areas of crowdsourcing maturity has been proposed. Third, the study identified the level of crowdsourcing maturity of the municipal offices in Poland. Therefore, it is claimed that this study directly responds to, expands, and deepens the earlier findings which have been limited to healthcare institutions only (Birch et al., 2014). Moreover, since in the previous literature there have been no studies on crowdsourcing maturity of municipal offices, it is claimed that the results obtained develop knowledge in this field.

It seems that this research is valuable to practitioners because it directly points to the key activities that allow municipal offices to benefit from crowdsourcing. This research shows that crowdsourcing requires appropriate and conscious management, which is associated with the improvement of specific skills, features, and capabilities of the organization in a specific area - hence the awareness of decision makers, at what level of crowdsourcing maturity they are and what actions they should take before crowdsourcing implementation is significant. The results obtained in the empirical research and proposed original crowdsourcing maturity evaluation sheet for the organizational, individual, and technological areas can be a response to postulates regarding conscious crowdsourcing management. The basis is to prepare the office for implementing crowdsourcing. In addition to the appropriate designing of the tasks transferred to the virtual community, issuing ordinances and procedures, selecting and matching of an appropriate crowdsourcing platform to the needs and expectations of the office or appointing an initiative coordinator as well as other activities specified in the proposed crowdsourcing maturity evaluation sheet – one cannot forget about the employees and management staff of the municipal offices. As the research results show, it is the motivation and engagement of the employees as well as the openness and support of the management staff that play a large role in the achievement of crowdsourcing maturity. According to this approach, the management takes the initiative, initiates a given action, initiates, is able to find the best solution, and actively and constantly searches for information to increase knowledge resources.

This research has certain limitations. First of all, the majority of respondents was management staff (79.44%), which may pose a threat of bias and subjectivism in assessing the situation. Second, it was limited to the study of municipal offices in Poland, which may weaken the universality of the results obtained and the analyses carried out. However, it should be highlighted that this is, as far as the author is aware, the only study of the importance of crowdsourcing maturity for organizational learning at municipal offices in Poland conducted so far. It is justified to repeat the research in other countries. It seems that such replication is needed not only to test our results and make comparisons between nations, but also to reveal the possible differences between municipal offices at the national level (Brabham, 2008). Third, a significant limitation of the conducted empirical studies is the use of an original research tool

for measuring crowdsourcing maturity, which was developed on the basis of literature analysis. It has not been used in previous studies. However, the reliability of the proposed scales has been verified based on Cronbach's alpha coefficient. It should be emphasized that research into crowdsourcing maturity is valuable because more and more offices are including crowdsourcing solutions into their development strategies (Clark et al., 2019).

FUTURE RESEARCH DIRECTIONS

The presented research results, despite their limitations, allow for proposing the directions for future research. There is a need to focus the research efforts on the following aspects: identification of the motives and barriers related to the use of crowdsourcing by municipal offices, key factors for crowdsourcing success. It is also worth considering multi-level empirical studies, taking into consideration the triangulation of researchers. The parallel implementation of research by several researchers is important here. Such an approach would enable mitigating the unconscious preferences of the researchers.

KEY TERMS AND DEFINITIONS

Crowdsourcing: The organization's operation, consisting in the inclusion of virtual communities, in the form of an open call via an online platform, in problem solving, implementation of innovations or creating ideas or other tasks so far only implemented by the organization's employees.

Crowdsourcing Maturity: The degree to which the organization's resources in the organizational, individual, and technological areas enable the implementation of crowdsourcing and achieving the assumed benefits.

Crowdsourcing Maturity Model: A set of different tools, practices, and activities that enable the assessment of a given organization's competencies in the area of crowdsourcing and improvement of key factors leading to achieving the assumed goals.

E-Government: Use of information technology in general to provide citizens and organizations with more convenient access to government information and services and to provide delivery of public services to citizens, business partners, and those working in the public sector.

Maturity: The degree of the organization's preparation for the implementation of specific tasks in a comprehensive manner and the implementation of the goals set.

Public Organization: A complex entity that has the features specific to all organizations. Its essence is constituted by distinctive specific characteristics of certain features, and in particular its orientation towards pursuing the public interest.

Social Participation: Participation of citizens in managing the affairs of the community of which they are members.

Theory and Practice of Search Engine Optimization

INTRODUCTION

The extensive range of information resources and services is certainly one of the most important features of the Internet while at the same time, web search is considered as a crucial application for managing the massive volumes of distributed web content. Beyond argument, search engines have made an enormous contribution to the web by making the process of finding information online a very quick and easy process. Today, major search engines are considered to be the most common and trusted tool or service to retrieve information from the Internet. Also, they are the primary method used for navigation for hundreds of millions of users worldwide and one of the most common online activities (Spink & Xu, 2000; Purcell, 2011; Purcell, Brenner, & Rainie, 2012). Studies have shown that a significant percentage of consumers turn to search engines first when shopping for products online or when information gathering really matters (Murga, 2017; Schwartz, 2018). The majority of Internet traffic depends largely on them and thus, web search is one of the best sources of traffic for any website (Safran, 2013; Giomelakis & Veglis, 2016; Brightedge, 2018). However, it is true that the vast majority of all search traffic comes from the first or the first pages of search results as users usually focus on the top ranks.

There are two ways an online user – customer will find a business website via a search engine: through a pay-per-click campaign (PPC) or through an organic result listing that is based essentially on what is called Search Engine Optimization or briefly, SEO. The latter can be defined as the process of affecting - improving the visibility of a website (or a web page) so that it ranks well for particular keywords in a search engine's "natural" or "organic" (un-paid) search results (Ledford, 2009; Potts, 2007). Generally, the earlier, and more frequently a site appears in the search engine results page, the more visitors it will receive from the search traffic. In other words, it is a set of techniques that take into account the evaluation criteria of search engines regarding website content and structure (Giomelakis & Veglis, 2015).

There have been plenty studies regarding online users' click behavior on search engine results pages. According to some results, about 90 percent of search engine users never read beyond the third page of search results while page two and three get only 5.59 percent of the clicks (iProspect, 2006; Petrescu, 2014). Also, the top listing in Google's organic search results receives 32.5 percent of the traffic, compared to 17.6 percent for the second and 11.4 percent for the third position (Chitika, 2013). Finally, websites listed on the first page in Google's results generate about 72 to 92 percent of all traffic from an average search (Chitika, 2013; Petrescu, 2014). From all the above, it is evident that if a website is not in the first search results page or even worse is absent from the top 30, it has almost no chance of being read by a user (Clay, 2006). As a consequence, and while more and more websites are indexed by search engines

DOI: 10.4018/978-1-7998-3473-1.ch093

and compete one another to ensure their own market share, it is clear that factors as the highest ranking and top of the results page become increasingly essential for businesses of all kinds (Enge, Spencer, & Stricchiola, 2015; Giomelakis & Veglis, 2015).

This chapter provides an overview of Search Engine Optimization, with a focus on its different characteristics and practices as well its history and how it has evolved over the years. In order to give a better understanding of the importance of SEO in the current state of the Internet and in information search, basic knowledge of how search engines operate along with their recent updates are also provided.

BACKGROUND

Search engines are software that catalogs the World Wide Web and provides search using keywords into their vast databases containing full-text indexes of web pages. Users actually search this database of retrieved web pages, not the World Wide Web itself. As a consequence, they manage to take rapid results something that would be impossible if engines were trying to search billions of pages on the web in real time (Veglis, Pomportsis, & Avraam, 2004). When users click on search results they retrieve the current version of a web page. It is worth mentioning that search engines consist of three parts: the web crawler or spider, the indexer and also the query processor (Mudgil, Sharma, & Gupta, 2013). The crawler systematically browses the World Wide Web, looks at every URL (Uniform Resource Locator) collecting keywords and phrases on each page, which are then included in a massive database. The crawler is also responsible for keeping indexed pages up to date (Ledford, 2009). Search engines start with a set of very high quality sites and then visit the links on each page (of those sites) to discover other web pages. This complex process repeats over and over again until the crawling is complete. Through links, web crawlers (i.e. automated robots) can reach the many trillions of interconnected documents (Enge, Spencer, & Stricchiola, 2015).

Search engines use algorithms so as to find and collect information about web pages. Generally, a search algorithm can be characterized as a problem-solving procedure that takes the problem (i.e. the users' word or phrase), sifts through a vast database of cataloged keywords with their URLs, and then returns a listing of best-matching web pages according to the search criteria. Search results (i.e. page ranking) usually depend on the perceived quality-importance of the page (quality score - links from other sites) conforming to the algorithm that's being used as well as on relevance (relevant terms/links) and several other factors such as frequency of keywords, location, age or click-through rates (Ledford 2009; Enge, Spencer, & Stricchiola, 2015). It is worth mentioning that in the case of Google, the famous PageRank (one of its oldest algorithms) is a quality metric used in ranking (one out of many) that measures the importance of web pages by counting the number and quality of links to a page (Page, Sergey, Rajeev, & Winograd, 1998; Grappone & Couzin 2008). PageRank (PR) is a numerical measurement (0–10, the higher the better) and in the past it was one of the most important factors. Google has continuously improved the way it uses links to impact rankings (one reason is to deal with link spam), and its current algorithm is not based on PR as it was originally defined (Enge, Spencer, & Stricchiola, 2015). However, it still has some value in SEO (Grappone and Couzin 2008; Slegg 2013; Giomelakis & Veglis, 2016). Also, it is true that PR had become an obsession for many SEO workers worrying about their numbers and examining closely the quality of every new link. The last Pagerank update was in December 2013 and on April 15, 2016 the search engine has officially shut down the PageRank data to public (Southern, 2016; Schwartz 2016b). In brief, search algorithms can be classified into three broad categories: on-page algorithms that measure on-page factors looking at the elements of every page (e.g. keywords in

content or meta tags), whole-site algorithms that focus on the relationship of site elements (e.g. anchor text, linking between pages or architecture of pages) and finally, off-site algorithms that explore the links between the websites. All these three types are generally part of a larger algorithm (Ledford, 2009).

Search Engines have evolved dramatically over time and they constantly “crawl” the web to update their databases with new information. According to statistics, Google is the world’s most popular search engine having the vast majority (over 2/3) of the global search engine market followed by Yahoo, Bing and Baidu, China’s most popular search engine (Statcounter, 2019; Netmarketshare, 2019). In a com-Score survey (2015) data showed that Google sites led the U.S. explicit core search market with 64.5 percent market share, followed by Microsoft sites with 19.8 percent and Yahoo! sites with 12.8 percent. Among them, it should be noted that YouTube, a video search engine (acquired by Google in 2006 and it is integrated in its search results), is today the world’s 2nd largest search engine after Google. From a user and SEO perspective, videos can increase user dwell time on a page, they are considered highly shareable and many people turn to them when they search. According to Cisco company, videos will make up 80% of all online traffic by 2021 as people seek for more video content (Lunden, 2017; Dean, 2018a; Fishkin, 2018; An 2018; Ansley, 2019).

HISTORY OF SEO

SEO constitutes a part of Search Engine Marketing (SEM) and it is considered one of the leading and most influential activities in the field of online marketing, hence there is a wealth of information and tools designed to train and support the community (Potts, 2007; Nigro, Balduzzi, Cuesta, & Cisaro, 2012; Daniel, 2018). Historically, the actual phrase “Search Engine Optimization” was possibly first coined in 1997 by an unknown person. Search guru Danny Sullivan found for the first time the term used in May 1997 in a meta tag on his website, Search Engine Watch. However, it is quite possible that it was used before that. Sullivan acknowledges Bruce Clay as one of the first people in the industry to popularize the term (Sullivan, 2004; Dover, 2011).

SEO has always been associated with the influence of search engine results and its creation is rationally connected with the creation of the first search engines in the early-mid 90’s. Danny Dover describes (2011) that early SEO experts used to take advantage of alphabetical (“AAA”, “1ForU”) and chronological (submit websites at certain times) order to get to the top of rankings. Since then, things have changed considerably. Search engines improved using more complicated algorithms and at the same time, SEO became a more profitable business. Over time, site owners started to identify the worth of having their websites highly ranked and visible in online search results. They also noticed that the higher their website ranked, the more people would click on their content. From a simple URL submission initially and use of unsophisticated tactics, companies started to implement strategies such as keywords insertion, link building (process of obtaining hyperlinks from other websites), and recently social media utilization and multimedia content.

From the early days of search engines until today many SEO users have attempted to deceive search engines in order to artificially improve their visibility. That is usually called as “black-hat SEO” and pertains to the use of strategies or tactics (e.g. excessive use of keywords, hidden text or pages) that are used to get higher rankings in an unethical manner, doesn’t obey search engines guidelines for webmasters or involve deception. In general, it is a practice that violates the search engines’ terms of service and possibly results in a website being banned from a search engine and affiliate sites (Grappone & Couzin 2008; Ledford 2009). A remarkable example of penalizing was Google removal of BMW Germany

and Ricoh Germany for using misleading tactics in 2006 (Cutts, 2006). As stated, search engines have evolved tremendously in recent years and one of the most basic reasons that their algorithms are in a constant change is due to the need to address “Black Hat SEO” and provide the best possible results. Thus, they developed more complex ranking algorithms, considering additional factors that were more difficult for webmasters to manipulate.

SEO CHARACTERISTICS

There are definitely myths about search engines. For example, that attaining a top spot in the organic, natural results requires actually paying Google and other search sites. On the contrary, a high position in search results requires actually worthy content coupled with time, effort, and skill (Potts, 2007). SEO can be applied to many different websites to some degree and can target different types of search, including image - video search, local, voice, news or academic search (Beel, Gipp, & Wilde, 2010; Giomelakis & Veglis, 2016; Wikipedia, 2016; Sentance, 2016a, 2016b; Dean, 2018a; Ansley, 2019). Arguably, it is very closely connected to e-Commerce websites (Malaga, 2007). According to relevant studies, 89 percent of consumers turn to search engines to find information on products, services or businesses before making purchases and 36 percent turn to search engines first when shopping online (Fleishman-Hillard & Harris Interactive, 2012; Schwartz, 2018). Given that it takes into account how search engines work and the actual terms that people search for, there are several factors that affect SEO (Dean, 2018b) but unfortunately, there is no magic recipe for the first page and certainly no guaranteed results. By contrast, there is a variety of things to consider that in conjunction can bring good results. Some of them can directly affect SEO while others can have an indirect impact on search rank. Everything has its value and Google, Bing or other search engines use them to evaluate and rank web pages in their results. Although there are differences in the ways various search engines work, the basic rules remain similar and a well-planned SEO strategy can usually bring good results in all major search engines (Giomelakis & Veglis, 2015).

SEO strategies can be divided into four main categories: keyword research/selection, search engine indexing, on-page optimization and off-page optimization (Malaga, 2008). *On-page optimization* refers to the management of all factors related directly to someone’s website (content – appropriate keywords, architecture and internal link structure as well as html elements). More specifically, this category contains among others, page titles (or HTML titles tag that usually appear in search results), on-page headlines, description of web pages (or meta description tag) and URL’s. Using main, appropriate words/phrases that people often use in their searches in all the above elements is crucial to SEO. However, it should be noted that the use of keywords to a great extent in the actual content of a web page is by all means not a key requirement. In contrast, it is effective when this happens naturally without boring the readers. Besides, keyword stuffing (i.e. the practice of overloading a web page’s content with keywords) can bring unpleasant results to a website (Giomelakis & Veglis, 2015). Furthermore, as mobile devices become more prevalent in daily life, a good user experience across all devices (desktop, tablet or smartphone) has become a significant consideration in SEO strategy (mobile SEO). Google has updated its algorithm in this direction (it took the name “Mobilegeddon”) given that in many countries around the world including the US and Japan, more searches take place on mobile devices than on computers (Makino, Jung, & Phan, 2015; Dischler, 2015; Sullivan, 2015; Sterling, 2016a; Gevelber, 2016; Barysevich, 2018; Statista, 2019). It is worth mentioning that in March 2018, the company announced the mobile-first indexing prioritizing and using the mobile version of a page for indexing and ranking (Zhang, 2018).

Examples of SEO practices:

- 1) Page titles/headlines
 - World Cup 2014: Brazil humiliated by Germany 7-1 in semi-final / Novak Djokovic beats Roger Federer in epic Wimbledon 2014 men's final (SEO-Friendly)
 - Germany's triumph in the semi-final / Djoko did it again! (Non-SEO Friendly)
- 2) Url's
 - www.newsandseo.com/2014/seo-best-practices-for-structuring-urls.html (SEO-Friendly)
 - www.newsandseo.com/2014/how-to-create-seo-friendly-urls.html (SEO-Friendly)
 - www.newsandseo.com/2014/new/item.aspx?itemid=3051.html (Non-SEO Friendly)
 - www.newsandseo.com/2014/forum/viewtopic/m-159327.html (Non-SEO Friendly)
- 3) Different titles/headlines

This practice is used by several news organizations (e.g. BBC News, Guardian, Huffington Post or New York Times) and the most common is the different headlines between home page or other Web site indexes and the story page itself (see figure 1). The latter that appears in search results, is usually more specific including more keywords for the topic.

Regarding *off-page optimization*, it includes all the efforts made away from someone's website like link building or social signal strategy. Links from other websites (called backlinks or inbound links) have great importance, serve as votes for the value and are a basic requirement for a web page to be found both from search engines and online searchers (Dean, 2016). In addition, it is highly important for inbound links to be qualitative, coming from well-known, trusted websites in order to give much more value and better evaluation. There are many different ways to gain inbound links such as articles/domain submission to directories (e.g. Dmoz), forum, blogs, and news aggregators as well as building relationships and links exchange with other websites. It is true that for a website with quality content, it is usually a matter of time until it gains many natural and qualitative backlinks. However, not only inbound links but also external links that lead to other relevant web pages (preferably credible and high-ranking sites) can contribute positively especially if a website is new (Giomelakis & Veglis, 2015).

SEO, DEVELOPMENT AND GOOGLE UPDATES

The development of the World Wide Web (Web 2.0) over the last decade has affected and brought significant changes in web content such as user-generated content and social web. Furthermore, search technology itself evolved over the last years with the growth of contemporary search engines something that has arguably affected SEO. For example, Google now provides different types of search results (e.g. the knowledge Graph next to the search results) or featured snippets. Featured snippets are the quick, direct answers at the top of the search results page (position zero) and a special way that Google shows off results in response to some search queries. They can come in different forms (e.g. a paragraph, a list or a table) and have a major impact on the search world (Sullivan, 2018; Schwartz, 2018). According to a recent study on clickstream, 49% of all Google searches end without a click (Fishkin, 2019). In this context, voice search looks like a fast-rising trend in search and SEO industry given that a significant percentage of all searches on mobile come from voice searches. The numbers are only expected to grow and thus, experts have already started to optimize their content for voice searching (Huffman, 2014; Sterling, 2016b; Sentance, 2016a, 2016b; Dean, 2018a; Ansley, 2019).

Nowadays, the optimization for search engines is not anymore only about link-building and keywords. Social media and social signals (such as Facebook Shares/likes) have increasingly become one of the

Figure 1. The dual headline system in BBC news

many factors search engines take seriously into account (Searchmetrics, 2013; Peters, 2013). In order to enhance their perfect reach, many search engines incorporate information from Web 2.0 services into their searchable indexes (Zimmer, 2008). For instance, active Facebook profile pages have many ranking possibilities for branded, subject-based and personal name-based queries at Google results. Also, due to Twitter's domain authority, its profile pages also rank highly for relevant searches. Results from Twitter can be used for queries where real-time data are helpful (Dover, 2011). Social signals, in general, have a positive impact on websites and are considered as the new link building metric as search engines increasingly search for social signals to help the ranking of pages (Rayson, 2013; Frasco, 2013). The more referrals someone has across the web, the more search engine spiders notice and categorize their content (Ehrlich, 2013). Social media and SEO do overlap, and the former can contribute to the total organic success of websites in several ways (Pascale, 2014).

Search engine algorithms have gone through many changes over the last decade having a great impact on SEO industry. Recent changes especially in Google have added more value to quality as well as content marketing that many experts have called it as the new SEO (DeMers, 2013). For example, the change of Panda algorithm (February 2011) was made in order to eliminate low-quality websites in favor of those with frequently updated, in-depth content. In the same vein, Google Penguin (first launched in April 2012 and since 2016 it is part of Google's core algorithm) was the response to "Black-hat" SEO and web spam and also Hummingbird (late 2013) added the contextual search, a way to interpret content by looking at the relationship between terms (Rampton & DeMers, 2014; Barysevich, 2018; Donnelly, 2019). The new age of search will be run by mobile. In this context, Google's mobile-friendly update in April 2015 was released in order to give priority to websites that display well on smartphones and mobile devices in general (Makino, Jung, & Phan, 2015; Barysevich, 2018). A few months later, on 26 October 2015 Google confirmed the use of RankBrain, a machine-learning artificial intelligence (AI) system and actually part of the overall Google's Hummingbird search algorithm. The system was created in order to learn from real user searches - behaviors and also to help the process and the interpretation of search queries by providing more accurate results for users. Along with links and content, RankBrain is considered today one of the top three ranking signals (Clark, 2015; Sullivan, 2016; Schwartz, 2016a; Ansley, 2019). Likewise, Bing launched in 2017 new intelligent search features powered by AI (Bing, 2017). Finally, Google's Pigeon (July 2014) and Possum updates (September 2016) were both made to improve the quality of local search results (considering the physical location of the searcher) and Google Fred was another recent update (March 2017) with purpose to down-rank websites that prioritize aggressive monetization over user experience (Barysevich, 2018; Donnelly, 2019). As regards local results, a strong local SEO strategy is crucial for reaching more customers given that 80% of consumers use local searches to find a product or service and 50% of them perform a local search and visit a store the same day (Kolowich, 2016; Drolet, 2017).

The world of SEO is constantly evolving and thus, SEO workers have to be always up to date on new developments and also utilize useful tools and services for their work. Tools such as Google Analytics (the most widely known web analytics package), Google PageSpeed Insights (analyzes the performance of a web page on both mobile and desktop devices providing optimization suggestions and information on how to improve the load time), Google Search Console (previously Google Webmaster Tools that enable webmasters to monitor and maintain their presence in search results), Google Trends (a tool to identify "hot" topics), SEMrush, Ahrefs tools, Ubersuggest or finally Moz tools are among others, very popular in SEO industry. It is crucial to understand that SEO is not only about engines but also making someone's website (and its content) user-friendly and better for people. The content is still the most important thing for any website and this has to be reliable and interesting. Even search engines look now for unique, qualitative and useful content that will satisfy and motivate readers to share it through social networks, blog posts or forums. In spite of how good is SEO, it is not likely for any website with useless content to get ranked well in the long term because no one is ever going to visit or look for it. Besides, Google and other search engines got much smarter and can distinguish between content with real value and content that exists only for SEO purposes.

FUTURE RESEARCH DIRECTIONS

Beyond argument, there are several important aspects in this field that require further study. For instance, the increasing involvement of social media in SEO strategy is an area of research that has to be studied

more in order to better clarify the relation between them. And that's because there is a strong indication that social networks and social media, in general, will continue to increase their significance and presence in the internet population. It is true that web search is increasingly becoming more personalized and user influenced. For many years, SEO and search results were all about keywords and link building. Nowadays, things are changed, the search results are arguably better and the search experience is much more advanced. SEO experts need to take the audience, their interests, user experience or what device they are using more into account when developing their strategies. All the above are issues that deserve more careful attention in future research because these are elements intimately related with search engines. In this context and as the web ecosystem evolves, the so-called mobile, local or vertical search-SEO has grown considerably gaining significant attention from field experts. Today, the mobile landscape has evolved to such an extent that it has become a completely unique (mobile-first) search environment. All these new types of SEO along with the opportunities they offer in online industry are areas that need to be addressed in future studies.

CONCLUSIONS

Undeniably, search engines have come a long way since their appearance in the early 90's. In this context, SEO grew out of the development of search engines and the World Wide Web. As the years pass, there is no question that search engines will continue to evolve their algorithms and make improvements in their ability to crawl and index new types of content such as multimedia, voice search or data coming from social media. In this vein, SEO practitioners will constantly deal with new ways of searching, new types of searches as well as new devices to search on and their role in a user's experience. Over time, there have been fundamental shifts in the SEO landscape and field experts see a shift away from traditional ranking factors to deeper analysis and factors such as quality, multi-form content, social signals and user experience in general (DeMers, 2013; Dean, 2018a; Ansley, 2019).

SEO has come a long way from the days of metadata, but even though the search arena has seen a lot of innovations from AI to voice, the core concept is still the same and factors such as links, quality content and website speed remain as strong and significant as ever forming the foundation of any SEO strategy. Undeniably, high-quality, useful content as well as optimal website speed (page load time is already a ranking factor) encourages people to spend more time on a site and this, in turn help improving SERP rankings as well as conversion rate (Dean, 2016; Wang & Phan, 2018; Ansley, 2019). It might be thought that SEO will always have a place in a web strategy as long as Google and other search engines continue to drive a great amount of traffic on the Internet. The tactics involved in optimization may change, but the need will always remain. It is evident that every business that has a web presence (or wants to get clients from the web) would be wise to think about a SEO strategy as well as the potential it creates in order to increase or maintain its position within the search results. Implementing SEO into a website is becoming more and more necessary in today's digitalized world. Given that people will always be on a quest for information, and given the marketing imperative to get your information seen and keep ahead of the competition, companies will continue to figure out ways to use SEO-related techniques for higher rankings. The good use of SEO certainly does not guarantee high traffic and top rank. Nevertheless, an effective strategy can play its role by helping companies to obtain the best results and take advantage of the benefits provided through the utilization of search engines and web search in general.

KEY TERMS AND DEFINITIONS

Click-Through Rate (CTR): The ratio of users who click on a specific link compared to the number of total users who view an email, a web page or an advertisement. It is used to measure the success of an advertisement campaign. For example, if an advertisement had 10 clicks and 1000 impressions (number of times it was served), the CTR would be 10% (clicks / impressions x 100).

Local SEO: The optimization process that focuses on results that are relevant to a user based on its current location.

Organic Results: Also called «natural» or un-paid. The results that appear because of their relevance to the search terms.

Social Signals: A kind of recommendations through social media. Social signals are the Facebook shares or likes, the tweets, Google +1s, pins or some other way of social media bookmarking or sharing.

User-Generated Content (UGC): Any form of digital content such as images, video, status updates or blogs that is produced and shared by users of an online service or website, often made available via social media websites.

Vertical Search: The search accessibility of specific segments and formats of online content. Vertical search services focus on specific topics such as news, restaurants, or products. Google provides also vertical search such as Google news or Google images.

Techniques for Developing Mobile-Friendly Web Sites

J. Christopher Sandvig

Western Washington University, USA

INTRODUCTION

This article describes the three most popular techniques for developing mobile-friendly websites. Such sites are designed to accommodate the physical limitations of mobile devices. These limitations include small displays, touch screens, low bandwidth, and high latency. To accommodate these limitations mobile-friendly websites format pages for vertical scrolling, provide larger touch targets such as buttons and links, minimize the amount of data that must be downloaded, may display less information than sites designed for desktops, and utilize space saving navigation techniques. The objectives of this article are to describe the attributes of mobile friendly websites and overview the most popular methods for developing them.

BACKGROUND

The growing use of mobile devices for e-commerce, product research, news, social media, and web search has created a need for mobile-friendly websites. In the early 2000's the majority of web traffic was from desktop devices and most websites were designed to be used with full-size monitors, keyboards, and mice. The introduction of the iPhone 2007 was the beginning of a rapid shift to mobile devices (Ebner, Stickel & Kolbitsch, 2010). By early 2013 users were spending more time online with mobile devices than with desktop devices (Marshall, 2015). Google reported in May 2015 that searches from mobile devices exceeded those from desktop devices in 10 countries, including the US and Japan (Dischler, 2015). By January 2018 mobile internet accounted for 52% of total worldwide web page views (Statista, 2019). With mobile devices accounting for over half of the world's web traffic it is important that websites be mobile friendly.

Researchers have found that the usability of mobile sites has a significant influence on user perceptions, user satisfaction, and trust (Casalo, Flavián & Guinalú, 2008; Lee, Moon, Kim & Mun, 2015). Mobile usability has also been found to have a strong influence on the buying behavior of consumers (Hsu, Perng, Chiou & Ou, 2014).

PHYSICAL LIMITATIONS OF MOBILE DEVICES

In this article the term mobile device is used to refer to smart phones and tablets. Desktop device refers to desktop computer and laptops. The two types of devices differ primarily by screen size and input methods. Mobile devices typically have smaller screens than desktop computers and cannot display as much information. Web designers can accommodate smaller screens by arranging content in screen-width columns that can be conveniently viewed with vertical scrolling. Mobile-friendly sites frequently display

DOI: 10.4018/978-1-7998-3473-1.ch094

less information, smaller images, and use more space efficient navigation. For instance, navigation options that are fully visible on a desktop computer may be put into a “hamburger menu” which the user may then expand to display navigation options (Moyers, 2018).

Mobile devices also use touch screens for user input rather than keyboards and mice. Touch screens require that tap targets, such as hyperlinks, buttons and forms, be large enough that a user can tap it with a finger. They must also have enough space around them so that users can tap individual items without accidentally selecting other tap targets (Brooks, 2017).

Figures 1 and 2 compare the same web page (<https://huxley.wvu.edu/>) in desktop and mobile formats. The desktop format (Figure 1) displays a large image with navigation menus both above and below the image. The five navigation options in the top menu and eight options in the bottom menu are all visible. The page content (not visible) uses both two and three column layouts.

Figure 2 displays the same page formatted in a mobile-friendly layout for an iPhone 8. The screen of this device is only 375px wide versus approximately 1500px for the desktop site. The two navigation menus have been replaced with a hamburger menu in the top right-hand corner. When the hamburger menu is tapped it opens to fill the screen and displays all of the navigation options. The large image is reduced slightly in size and only about 30% if it is displayed on the mobile device. The page content (not visible) is displayed in a single column that is approximately 11 screens tall. On this particular page the mobile layout displays the same content as the desktop layout but it is common to display less content in mobile layouts.

Figure 1. Example of desktop layout

OUR DIFFERENCE

Since 1969, WWU's Huxley College of the Environment has enjoyed a reputation as a premier institution for the education

Figure 2. Example of a mobile layout

OUR DIFFERENCE

Mobile devices have additional limitations besides small touch screens. Mobile data speeds are typically much slower than those of desktop computers connected to a broadband network. For mobile devices average download speed in the US during the first six months of 2018 was 27 Mbps (Megabits per second) (Murnane, 2018). In contrast, the average download speed in the US for broadband networks was 96 Mbps. Everything else being equal, the lower bandwidth of mobile networks causes download times to be more than three times greater than those of broadband networks (Speedtest, 2018).

Mobile networks also have greater network latency. This is the time it takes for a server to send a packet of data to a client. The greater the latency the longer it takes a web page to load. Web designers can minimize the negative impact of latency by minimizing the number of resources that must be downloaded to render a web page.

TECHNIQUES FOR DEVELOPING MOBILE-FRIENDLY WEB INTERFACES

The physical limitations of mobile devices can be mitigated by using design techniques that accommodate the small screens, slow download speeds, and touch screens that characterize these devices. Currently there are three popular mobile-friendly design techniques: responsive, dynamic serving, and separate URL. These techniques go by a variety of names so this paper will use the naming conventions used in the Google Developer's Guide (2019). All three techniques are utilized by major websites and have distinctive advantages and disadvantages that are discussed later in this article.

Responsive Technique

The responsive design technique sends the same content to both desktop and mobile devices. It then employs CSS (cascading style sheet) media queries to adapt the content and layout to the physical attributes of the device. CSS media queries are executed by the client's web browser when the page is being rendered.

Media queries can check for device attributes such as screen height and width and allow the conditional application of formatting styles. Figure 3 illustrates the use of media queries to switch between a two-column layout and a one-column layout depending upon the width of the screen. Lines 2-5 of the example defines a class named “column” that is 50% the width of the screen and floats to the left. This style creates a two column layout. Lines 8-12 use a media query to modify the “column” class for small screens. When the screen size is 600px or less it redefines the column class to be 100% the width of the screen. The right column is then displayed below the left column creating a tall single-column layout.

Figure 3. Media query conditional layouts

```

1  /* two columns that float next to each other */
2  .column {
3      float: left;
4      width: 50%;
5  }
6
7  /* One column for screens 600px wide or less */
8  @media screen and (max-width: 600px) {
9      .column {
10         width: 100%;
11     }
12 }
13

```

The responsive design technique has several advantages versus the other two popular techniques discussed in this article. Responsive designs are relatively easy to implement and maintain (Nebeling& Norrie, 2013). Greatly simplifying the implementation of the responsive technique are a number of open-source CSS frameworks that provide pre-defined formatting styles. Web developers then apply the styles to control layout and provide mobile-friendly layouts. These frameworks are referred to as “grid frameworks” because they provide styles for a fixed-number of pre-defined columns, typically between 9 and 16. Web designers then select the number of columns needed to achieve the desired layout.

There are dozens of free open-source grid frameworks available. They differ primarily on the number of features provided. Smaller frameworks such as Milligram, GRD, and Skeleton provide grid layout features but little else. The advantage of these “light” frameworks is that they require smaller CSS files, download more quickly, and load more quickly in the web browser. Larger full-featured frameworks such as Twitter Bootstrap provide not only a grid framework but styles for forms, fonts, color themes, responsive navigation features, and jQuery plugins. The downside of using a full-featured framework is

that the CSS and JavaScript files can be relatively large. Twitter Bootstrap is currently the most popular CSS framework (Saring, 2018)

Media queries are a relatively new addition to the tools available for developing mobile friendly websites. They were added to the CSS3 specifications in 2012 but it then took several years for web browsers to fully implement them. Early adopters of media queries had to accept that a substantial percentage of their users would not have a good mobile experience. However by 2019 browser support for media queries is almost universal. As of March 2019 CSS media queries were supported by the web browsers being utilized by 98.2% of global users (CanIUse, 2019).

Dynamic Serving Technique

The dynamic serving technique sends different content to different devices. The advantage of this technique is that content can be customized to the strengths and limitations of the requesting device. For instance, the content sent to a mobile device may include smaller images, layout appropriate for a small screen, larger tap targets, less content, and mobile-friendly navigation. In contrast the content sent to a desktop computer may include richer content, more navigation options, multi-column layout, and larger images.

The disadvantage of the dynamic serving technique is that the server must accurately determine the type of device so that it can serve appropriate content. The server identifies the device by examining information which is included with each request. The World Wide Web Consortium (W3C) standards for HTTP (hypertext transfer protocol) requests include information on the user's browser, or the user-agent. From information included in the user-agent string the server can determine what type of device sent the request. For example, the following user-agent string is for a Chrome browser running on a Samsung Galaxy S5 mobile phone:

User-Agent: Mozilla/5.0 (Linux; Android 5.0; SM-G900P Build/LRX21T) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/73.0.3683.103 Mobile Safari/537.36

Determining device attributes from the information contained in the user-agent sting can be challenging and error prone. For instance, the user-agent above starts with the word "Mozilla/5.0" which is a term that dates back to the early days of the Internet and the Netscape browser. It also includes the terms AppleWebKit, Chrome, and Mobile Safari. Of the four identifiers only Chrome/73..." identifies the browser being used. An article by Nicholas Zakas titled "History of user-agent sniffing" (Zakas, 2010) concludes:

The history of the user-agent string is marked by browsers trying to convince user-agent sniffers that they are what they are not. Internet Explorer wants to be identified as Netscape 4; Konqueror and WebKit want to be identified as Firefox; Chrome wants to be identified as Safari. This can make user-agent sniffing a bit more difficult...

Once the server has identified the type of browser the next step is to determine the device and its capabilities. The user-agent string usually provides limited information about the device. In the example above the identifier "SM-G900P" can be used to determine that the request was sent from a Samsung Galaxy S5 phone. The server can use this information to lookup the screen size and other physical attributes of the phone and use this information to dynamically generate appropriate content. However there are thousands of phone models in use worldwide and new models are frequently being released. It can be challenging and time consuming for website owners to maintain lookup tables for all of the

devices being used worldwide. So while the dynamic serving technique can provide content optimized to the device it can be a challenge to accurately identify the device and its capabilities.

Separate URL Technique

The separate URL technique utilizes two or more separate websites, with each site optimized for devices with different attributes. This technique is also referred to as m-dot, since the URL of the mobile optimized sites often use “m.” rather than “www.” for the third-level domain name. The advantage of this approach is that content can be optimized for the capabilities of each device, similar to the dynamic serving technique.

This approach has a few disadvantages. One is that like the dynamic serving approach the server must examine the user-agent to determine what type of device sent the request. Once the requesting device is identified the server redirects the user’s request to the appropriate website. As discussed in the previous section, correctly identifying the device and determining its capabilities is challenging and error prone.

Another disadvantage of the approach is that the redirecting the user’s request to a different site requires a round-trip back to the requesting device which slows page load time. Another disadvantage is the cost of maintaining two or more websites.

Other Mobilization Techniques

In addition to the three primary mobilization technique described above there are a few other techniques which can be quite effective. For instance, the responsive technique may be combined with the server adaptive technique in a technique called RESS, responsive web design with server-side components. As its name suggests it uses the responsive technique combined with the dynamic serving technique to send device-appropriate content, such as smaller images (Hogan, 2014; Firtman, 2016). This technique enjoys much of the simplicity of the responsive technique while also allowing for server optimization of assets such as images (Yousaf, Butt, Azam, & Anwar, 2018).

Another hybrid technique, JavaScript adaptive, uses JavaScript on the client device to identify device capabilities. It then makes requests to the server for device appropriate resources. It is similar to the server adaptive technique except it adapts the content on the client instead of on the server. This approach also eliminates the need to correctly identify the device based upon the user agent. The JavaScript adaptive technique may be implemented through open source frameworks such as Mobify.js (GitHub 2019a) and Response.js (GitHub 2019b).

A more recent technique that is being promoted by Google is accelerated mobile page (AMP). AMP is set of design rules that can significantly reduce page download times. It is an implementation of the separate URL technique where the mobile site implements AMP design standards. AMP standards prohibits the use of page-slowng assets such as external styles sheets and JavaScript. It requires the use of AMP JavaScript to optimize page load times. Sites that employ all of the AMP design standards are rewarded by Google search with higher search rankings and free caching by Google’s global network of AMP cache servers. AMP pages are also identified in Google’s mobile search results with the outline of a lightning-bolt inside a gray circle. The AMP standard was introduced in 2016 and by early 2019 it was being used by over 31 million domains (Jones, 2019).

Given the advantages and disadvantage of various mobilization techniques it is challenging for website owners and managers to decide which approach is most appropriate for their needs. The next section

addresses the trade-offs for the different approaches and provides guidelines for selecting a mobilization technique.

SOLUTIONS AND RECOMMENDATIONS

Selecting the most appropriate mobilization technique for a particular website depends on a number of factors. These factors include budget, available technical expertise, existing site design, and the needs of site users. The responsive technique is relatively inexpensive to implement and maintain but, unlike the adaptive and separate URL approaches, it does not optimize images and other assets to the device.

The server adaptive and separate URL approaches require more technical expertise to implement and maintain than the response technique but can provide a better user experience (Yousaf, Arshad, Nouman & Arshad, 2018). Both techniques depend upon interpreting the cryptic information provided in the user-agent string to determine device capabilities. Sites which are able and willing to invest in technical expertise are able to translate this information with a high degree of accuracy. These techniques also require tools on the server to modify the content sent to the client. With the adaptive approach this is achieved with server-side programming tools such as PHP, Python, or ASP.NET.

The responsive technique is a popular choice for many sites due to its low development and maintenance cost. Google recommends this technique for most sites while also acknowledging its limitations (Google Developer's Guide, 2018). However for sites where it is imperative to provide an optimized mobile experience the server adaptive may be a good choice. For instance, the pages that display Google's search results generate a significant fraction of the company's revenue and almost 60% of search requests originate from a mobile devices (Sterling, 2016). So while Google recommends responsive for most websites its own site uses server adaptive for displaying search results.

The choice of mobilization technique is complicated by the rapid evolution of both web and mobile technologies. Google's AMP standard illustrates this rapid evolution. The AMP standard was introduced in 2016 and by early 2019 it was being used by over 31 million domains. In addition mobile devices and mobile networks are also becoming faster and more capable. Mobile devices are trending toward larger screens and each generation of mobile device has more processing power. The current generation of 4G mobile networks are approximately six times faster than 3G networks and 5G networks are expected to be significantly faster (Ilumda, 2019). The changing mobile landscape has implications for mobile web development. As phones and networks become faster the importance of optimizing sites for fast download speeds may become less important. Conversely as mobile users become accustomed to faster page load times they may become less tolerant of sites that do not load almost instantly. Website designers need to be attentive to such trends.

One approach to deciding upon a mobilization technique is to examine which techniques other sites are using. A study by Sandvig (2016) of 527 leading global e-commerce sites found that the separate URL technique was the most popular used by 44.1% of sites, followed by server adaptive utilized by 23.8% of sites, and responsive utilized by 23.0% of sites.

A 2015 survey by Pure Oxygen Lab of 500 e-commerce sites found results similar to the Sandvig study. It found that the separate URL technique was the most popular, utilized by 59% of sites in 2014. Server adaptive was the second most popular at 15%, and responsive the third most popular at 9%. This study also examined trends in technique utilization. It found that between 2013 and 2014 use of separate URL utilization declined by 20% while server adaptive increased from 12% to 15%. Use of the responsive

technique almost tripled from 3% to 9% (Klais, 2015). So while in 2014 the separate URL approach was by far the most popular technique for e-commerce sites its usage was declining rapidly.

A longitudinal study of 37 academic library sites found that in 2015 73% were using the responsive technique, up from 32% in 2013 (Comeaux, 2017). Given that most university library websites have smaller budgets than sites like Google and Amazon it is not surprising that they favor the relatively low cost of the responsive technique.

Overall there is little rigorous academic research on the use of mobile development techniques. A recent article on mobile usability by Hoehle and Venkatesh (2015) observes many gaps in mobile usability research. These gaps include a lack of rigorously developed survey instruments, a lack of context-specific instruments for holistically measuring mobile usability, and few performance attributes measured in isolation. These shortcomings in the literature provide a poor understanding of the antecedents for mobile application usability.

The decision on which mobilization technique to utilize is complex and there are no definitive guidelines that can be applied to specific situations. For websites with limited development and maintenance budgets Google's recommendation of using the responsive technique is likely a good choice. For high traffic sites such as the large e-commerce sites surveyed by Sandvig and Pure Oxygen Labs it may be worth investing in a technique that provides a more optimized mobile experience.

FUTURE RESEARCH DIRECTIONS

The trend toward greater utilization of mobile devices is likely to continue and provides a myriad of possibilities for mobile usability research. This article has discussed a number of techniques for developing mobile-friendly websites and explored the limited research available on website mobilization techniques. Given the importance of the topic there has been very little empirical research on the utilization or performance of different mobilization techniques. Site managers and web users would both benefit from a more robust research agenda on the topic of website mobilization. A few future directions for research on the topic include:

Usage: Managers must make expensive long-term decisions on which mobile design technique(s) to employ but have only limited information on which techniques are currently employed. Additional research on technique usage, trends, and costs would help them make more informed decisions.

Performance: There is little research that provides rigorous analysis of the performance of mobilization techniques with respect to usability, reliability, and page rendering times. Techniques that adapt content on the server are usually going to be faster but there are few if any rigorous head-to-head comparisons.

Cost: Managers must weigh site performance to the cost of development and maintenance. For many non-profits and organizations with limited budgets the responsive technique is the obvious choice because of its relatively low development and maintenance costs. However for organizations where mobile web is an integral part of their business, such as many on-line retail sites, the decisions are more complicated. Managers of such sites would benefit from research exploring the cost-performance tradeoffs.

Trends: The rapid evolution of mobile devices, mobile networks, user expectations, and development technologies create a moving target for managers. Predicting technology trends is challenging

but managers who are making major investments in mobile web technologies would benefit from skillful projections made by well-informed experts.

CONCLUSION

This article has covered the three most popular web mobilization techniques: responsive, dynamic serving, and separate URL. It has also discussed hybrid techniques, such as combinations of responsive and dynamic serving, and Google's APM standards. In selecting a technique managers must examine the trade-offs between performance and the cost of development and maintenance. Despite the importance of the topic to managers of many types of organizations there is a surprising lack of rigorous research to guide their decision making.

KEY TERMS AND DEFINITIONS

Cascading Style Sheets (CSS): A standardized scripting language used for styling web content. CSS is interpreted by the client's web browser. Web designers use it to specify web page layout, colors, fonts, backgrounds, spacing, and other stylistic features. The most recent standard, CSS 3, includes a feature called media queries which allow web designers to specify styles for specific device characteristics such as screen height and width, orientation (vertical or horizontal), and resolution. Web designers can use media queries to apply different layouts and styles based upon device characteristics.

Client-Server Network: The internet is network of connected client and server computers. Clients are the devices used by web users to make web requests. Client devices include desktop and laptop computers, tablets, and mobile devices such as phones. Web clients also include smart devices such as security cameras, appliances, lighting systems, and HVAC (heating, ventilation, and air conditioning) systems. Servers are computers that respond to web requests. They are typically identified by unique domain names, such as Google.com or Amazon.com.

HTML: Hypertext markup language is a scripting language that describes page content to web browsers. It is used to create navigation elements, paragraphs, display images, create hyperlinks, and form elements such as textboxes and buttons. It is styled using CSS (cascading style sheets).

JavaScript: A programming language that is executed by web browsers. Web developers can use it to identify device attributes, change page layout and styling, make web requests for images and cascading style sheets, and create responsive navigation. It is the only programming language used by all web browsers.

World Wide Web Consortium (W3C): The primary standards organization for the world wide web. It consists of over 475 members, including businesses, universities, governmental entities, and nonprofit organizations. Its members propose and adopt standards for browsers, HTML, CSS, web requests, web responses, security, and many other essential features that provide interoperability across devices on the internet.

Internet Banking Encounter Quality of Arab Middle East Banks: Organizational Determinants

INTRODUCTION

Online banking services was first provided in the early 1980 by Bank of Scotland and the Nottingham Building Society. Nonetheless, these services were discontinued because it was not widely accepted by the bank's customers. In the early on 1990, the banks start again adopting internet-banking services with the rapid growth of electronic services and information technology (Tait & Davis, 1989). Internet banking is a virtual banking service as online depositing, withdrawal and transfer of cash (Santos, 2003). Nowadays, online banking services have become an attractive and desirable alternative to the growing number of customers because they offer many benefits, such as low cost, save time, and easy to use. The essential success for service providers is expanding and retaining their e-customers and can do this by better understanding how customers can handle and evaluate the quality of the online banking service encounter (Mauro, Hernandez & Afonso, 2007).

The Middle East region will have extraordinary advantages from the e-banking services, particularly with high demand and development in the banking industry. So banks have begun to grow their branch systems and provide a wide range of service delivery channels, for example, call centres, internet banking, mobile banking, and ATMs. The rapid expansion of online banking services is most remarkable in the developed countries where the availability of smart phones and computers with simple access to internet enables adaptation of online banking easier for banks. Despite the fact that, this adoption still faces some limitations, efficient banks that located in urban areas are more likely to adopt online banking services (Jenkins, 2007).

The recent research by McKinsey on urban consumers in UAE and KSA (primarily focusing on internet users - UAE currently has 92 percent internet penetration while KSA has 65 percent) shows that at least 80 percent of these consumers now prefer to do at least some of their banking on computers, smartphones and tablets, and visit branches and call service hotlines only to meet specific and more complex needs. Despite the growing of e-channels in the Arab Middle East region, the physical channels – branches and ATMs – will continue to play major roles in banking across the region. Banks will have to balance regulatory demands and consumers' needs for a physical presence against the cost, reach and convenience advantages of digital services (Shirish, Jayantilal & Haimari, 2016). Therefore, there is a need to understand the quality of service encounter dimensions and examining determinants that affect the internet banking adoption to better satisfy the customers wants. This study investigated the

DOI: 10.4018/978-1-7998-3473-1.ch095

organizational determinants that could influence the bank's quality, for example, the impact of ownership structure (local or foreign), age of bank, size of bank determined by number of employees, the global presence and on the quality of bank website.

This study was conducted to accomplish the following objectives:

- 1- Reporting the quality of internet banking services encounter in the Arab Middle East region.
- 2- Identifying impact of bank ownership, size, age and global presence on the internet banking service encounter quality across countries in the Arab Middle East region.

This chapter was issued in the following sections; the first section discussed the research problem and contribution, followed by the research framework, the research methodology adopted, then, the findings and results were presented, next, these findings were discussed in the discussion section, followed by the implications and future researches, and finally a conclusion section summarize the main findings and contributions of this chapter.

RESEARCH PROBLEM AND CONTRIBUTION

During the last decade, electronic service quality has become a popular area of investigation by both researchers and practitioners. E-service quality can potentially increase online competitive advantages; therefore, it has a great effect in determining the success or failure of electronic services. Service quality, which is usually measured by how the service was received and matched customer expectations. Accordingly, researchers developed multidimensional service quality evaluation tool known as SERVQUAL (Santos, 2003). Banking websites have been evaluated from various perspectives using many criteria. Some researchers have proposed a model to assess the quality from the users viewpoint, while other researchers have proposed a specific framework model for website evaluation such as Diniz's model or Herey's model (Hasan & Abuelrub, 2008).

The service encounter is the interaction point between the service provider and customer, it is a virtual encounter in the context of e-banking in general and internet banking in particular, the proper design of this encounter is crucial element for the success of e-banking, since e-banking is a self service depends on the personal customer interaction with the system, accordingly, the banks should concern about developing the design of this encounter in order to give the customer more positive service experience. However, the service encounter design could be affected by many factors, internally and externally, for example, the customers (users) characteristics, type of service, the number of service routes, the organizational factors as the size of organization, the global presence...etc.

The most of previous studies of e-banking and internet banking in particular have investigated the degree of customer acceptance to adopt of the internet banking (e.g. Afshan, Sharif, Waseem & Frooghi, 2018; Safeena, Kammani, & Date, 2018; Khedmatgozar & Shahnazi, 2018; Yuan, Lai & Chu, 2018), also the perceived quality of internet banking service from the customers view point has been widely investigated (e.g. Ray, Ghosh, & Sen, 2017; Ray, 2017), and the impact of quality of e-banking on customers satisfaction (e.g. Ali & Raza, 2017; Firdous & Farooqi, 2017). Examining the determinants will help the decision makers in controlling or improving these determinants. The determinants examined by previous studies were mainly personal customer's determinants or user determinants for adopting or using e-banking (e.g. Alalwan, Dwivedi, & Rana, 2017; Oruç & Tatar, 2017). Very limited studies have investigated the determinants of internet banking service encounter quality (e.g. Migdadi & Al.Omari, 2017), and most of studies have investigated the cases in one country context.

RESEARCH CONCEPTUAL FRAMEWORK

In order to have a highly competitive internet banking service, it is important to understand the dimensions of service quality. The internet banking services are provided via the bank's website. The website is the interaction point between the customers and the bank, so investigating the quality dimensions of bank's website is the concern of this research. Online banking website quality has studied from various perspectives using many criteria. Some researchers have proposed a model to assess the quality from users point prescriptive. While other researchers have proposed a specific framework model for website evaluation such as Diniz model or Herey's model (Hasan & Abuelrub, 2011).

SERVQUAL model was developed by Berry, Zeithalm, and Parasuraman and used to assess service quality (Parasuraman, Berry & Zeithaml, 1993). Many measurements followed the principle of SERVQUAL such as BANKSERV. It contains of seventeen items on four dimensions, which are; conduct, communications, customer accessibility, and credibility (Al-jazzazi & Sultan, 2014). Some recent studies associate that SERVQUAL is a traditional instrument for assessing the service quality, which requires a little modification in order to suit the customers' wants (Jun & Cai, 2001).

Another model, which is called WebQual model is used for rating website on twelve dimensions, the focuses, is only on the rating quality of website from technical side rather than from customers' experience (Loiacono, Watson & Goodhue, 2002). More comprehensive measurement of the electronic service quality has developed by the E-S-QUAL model; this model has two different scales, the first with twenty-two items on four dimensions, which are efficiency, privacy, system availability, and fulfillment. The second scale includes nine items covered three dimensions relevant to the customer encounters with the website and they are compensation, responsiveness, and contact (Sadiq & Shaikh 2008).

Different website's quality dimensions have been investigated by the previous studies; some studies have investigated trust, empathy, and responsiveness from the customers' viewpoint (e.g. Agarwal & Venkatesh, 2002; & Chiu et.al, 2005). Other studies have investigated accessibility, navigation, security and response time (e.g. Webb & Webb, 2004). While other researchers have focused on the information quality as accuracy, understandability and richness (e.g. DeLone and McLean 2003; Cebi, 2013).

Website designers are encountering complex questions regarding how to design popular and attractive pages. Abels et al. (1999) suggested six operational definitions for using criteria such as content, structure, linkage, search and appearance. While Dholakia and Rego (1998) proposed a list of features that are considered important such as the number of links, the frequency of changes, number of pictures etc. The literature describes a number of quality dimensions of service encounter that can help to evaluate websites. The explosion of the internet has created the need for a method to measure and assess the features of websites such as usability and accessibility of a web application, where the goal is to make a website useful, gainful, user linking, and accessible to all.

The literature presents six main service quality dimensions which are; **functionality** (i.e. Cebi, 2013; Liébana-Cabanillas, Muñoz-Leiva, &Rejón-Guardia,2013). **Accessibility** (i.e. Godwin-Jones, 2001; Webb & Webb, 2004; Migdadi, 2008; Ahmad & Al-Zu'bi, 2011; Cebi, 2013; Liébana-Cabanillas, Muñoz-Leiva, &Rejón-Guardia, 2013; Hasan & Abuelrub 2008). **Navigation** (i.e. Webb & Webb, 2004; Migdadi, 2008; Hasan & Abuelrub, 2008; Sadiq & Shaikh,2008; Cebi, 2013). **Content** (i.e. Migdadi, 2008; Hasan & Abuelrub 2008; Sadiq & Shaikh, 2008; Ahmad & Al-Zu'bi, 2011; Carlos Pinho, de Lurdes Martins, &Macedo, 2011). **Customization** (i.e. Hasan & Abuelrub, 2008). Finally the main important dimension is the **security** (i.e. Webb & Webb, 2004; Sadiq & Shaikh, 2008; Hasan & Abuelrub, 2008; Sadiq & Shaikh, 2008; Polasik & Piotr Wisniewski, 2009; Keffala, 2010; Carlos Pinho, de Lurdes Martins, &Macedo, 2011; Ahmad and Al-Zu'bi, 2011; Cebi, 2013). In conclusion, after in-depth

revision of the available literature and models, the comprehensive quality dimensions are those listed above. These dimensions were investigated by this study. For more details about the definitions of the quality dimensions please see Table (1).

Table 1. Quality dimensions' definitions

Dimension	Definition	Reference
Functionality	The purpose of website whether as informational, relational or transactional	Liébana-Cabanillas, Muñoz-Leiva, &Rejón-Guardia (2013)
Navigation	The efficiency of websites in transforming information depends on the designer's easiness of design and the target audience	Cebi (2013)
Accessibility	The technique, which maximizes the ability of users to access services and information It is generally related to the implementation of website content in a way that allows users to access their information and service	Liébana-Cabanillas, Muñoz-Leiva, &Rejón-Guardia (2013)
Content	Web content is the visual, textual or aural useful information that is encountered as part of the user interaction on websites	Carlos Pinho, de Lurdes Martins, &Macedo, (2011)
Customization	The process of tailoring the content of a website based on the needs of users	Hasan & Abuelrub (2011)
Security	Security a dimension concerning about protection of users from fraud and risk of financial loss	Polasik & Piotr Wisniewski (2009)

Firm characteristics such as organization ownership structure, size, age, global presence are often considered important contextual dominants that may affect the quality of management practices in organizations (e.g. Hassan, Mohamad, Khaled & Bader, 2009) Table (2) shows the definition of bank's organizational characteristics. There is enough scientific literature that investigates the impact of ownership on the quality of traditional banking, while there are few researches that explore this issue for internet banking. Malhotra and Singh (2007) argued that there is a statistically significant relationship between the type of bank and e-banking services, while many studies have argued that the relationship between ownership and bank quality is complex, for example, Zu, Zhou, Zhu, & Yao (2011) mentioned that a company's ownership is widely suggested as critical determinant for sophisticated management techniques and it would be very difficult to found continuous enhancement in an organization without building strong quality culture.

Table 2. The measurement of bank characteristics

Bank characteristic	Measurement
Ownership	Local bank Foreign bank
Age	The years old since its established
Size	Number of employees working in the bank
Global presence	The bank has branches across boards

Most of the researches have indicated that national banks have a negative impact on the efficiency and productivity and it is linked with poor competence and higher corruption (i.e. Shleifer and Vishny,

1997). Limited studies mentioned that, government ownership is positively related to bank effectiveness. Ownership structure (Local or Foreign) is an important element for a healthy banking system (Boubakri, Cosset & Fisher, 2005). Foreign banks in developing countries performing better than their locally owned counterparts do. Moreover, foreign banks may have a tendency to achieve effective monitoring, propose a superior contact to technical, financial resources, managerial talent and thus supply the increasing bank's performance (Leech & Leahy, 1991).

H1: There is a significant differences between local and foreign banks in the quality of internet banking service encounter at the significant level ($\alpha \leq 0.05$)

The age of bank is an important determinant for the quality of internet banking from two aspects; first, it reflects the accumulation of experience, second the older banks are more capable to manage the perceived risks. On the other hand, new banks are likely to be more flexible in adopting the new technologies since it does not have to face the managerial obstacles of adopting new technologies within legacy system or need a large amount of money to install these services (Malhotra & Singh, 2007). In addition, banks that have between three to five years of services are more expected to fail rather than older banks (Hendrickson, Nichols & Fairchild, 2014). In order to survive in a competitive industry, new banks should work hard to improve their revenue, cost and profit efficiency. Therefore, old banks require a kind of reorientation to improve their abilities for surviving in the competitive industry (Hassan, Mohamad, Khaled & Bader, 2009). Younger bank have lower branch intensity so they more likely to adopt new technologies (Malhotra & Singh, 2007).

H2: There is statistically significant relationship between the age of bank and the quality of internet banking service encounter at the significance level ($\alpha \leq 0.05$).

Larger banks have more market share, capital and revenue in comparison with smaller banks, so they have competitive advantages to adopt more e-banking channels at lower cost and in appropriate way in comparison with smaller banks (Malhotra & Singh, 2007). Larger banks have more assets, higher branches intensity and more operating expenses, so they are more adopter for e-banking channels to reduce these burdens (Abiodun, 2013; Malhotra & Singh, 2007; Hassan, Mohamad, Khaled & Bader, 2009), while other studies as the study of Hassan, Mohamad, Khaled & Bader (2009) have not found a significant relationship between size of banks and the adoption of e-banking channels.

H3: There is a statistically significant relationship between the size of bank and the quality of internet banking service encounter at the significance level ($\alpha \leq 0.05$).

Banks branches intensity is one of the main characteristics that influence the adoption of internet banking. The more intensively the banks branched could potentially increasing the efficiency and saving the costs (Hendrickson, Nichols & Fairchild, 2014). Hence banks that having larger branches may have higher possibility for adopting online banking and will probably decreases the branches networks (Hirtle & Stiroh, 2007). In addition, using internet banking will eliminate the geographical boundaries (Acharya, Kagan & Rao Lingam, 2008).

H4: There is statistically significant relationship between the bank's global presence and the quality of internet banking service encounter at the significance level ($\alpha \leq 0.05$).

RESEARCH METHODOLOGY

The methodology adopted by this study was quantitative content analysis of banks websites. The methodology passed through different stages; the sample design, data collection process, and data analysis, the following sections discuss these phases in details.

First phase: Sample design

The bank is the unit of analysis; accordingly, the population of this study includes 375 banks, 226 local and 149 foreign banks. Since the population size is too big a representative sample was chosen. Table 3 shows the population and sample of the study. A sample size of 50 bank's websites in the Arab Middle East region was surveyed. This study endeavors to gather information through the multi-stage sampling method. Analysts normally utilize this technique of sample design when a complete list of the population does not exist or it is hard to gather.

Table 3. Population and sample of the study

Total Numbers of Banks		Country Name
Sample	Population	
3	30	Jordan
2	21	Kuwait
9	57	Iraq
14	73	Emirates
6	46	Bahrain
2	25	Yemen
6	46	Lebanon
2	24	Saudi Arabia
2	21	Qatar
2	16	Oman
2	16	Syria
50	375	Total

Second phase: Data collection

The data collection includes a descriptive and objective approach. Two data collection instruments were developed for this purpose. The first one is a questionnaire, which was directed to the experts in order to weigh the quality dimensions. This questionnaire was developed by reviewing the literature; the number of questionnaire items was nine. The rating scale of this questionnaire was five points Likert scales as follows: (1) not important at all, (2) not very important, (3) somewhat important, (4) important, (5) very important.

The second questionnaire was developed also by using the literature review; the main sources were Migdadi & Omari (2017), Migdadi (2008) and Miranda, Cortés & Barriuso (2006). The scale of the majority of the second questionnaire items is nominal according to the availability of function or the

attributes. Some item's scales were ratios as the number of times the websites have been updated, the age of online banks, the number of internal and external links etc. After developing the data collection instrument the data collection process was running as following:

First: specialists who have distinctive specializations were chosen to estimate the weight of various dimensions. The data collection was a structured interview whether face to face, or by telephone. Those experts were academics, IT experts, IT security administrators, software engineers, website developers, system administrators and bankers.

Second: The facts related to quality of banks' websites were collected by the direct observation of the websites and recording these facts on the second questionnaire. Then these facts were rated. Not all attributes were collected by using direct observations, other tools which are presented in Table (4) were used to collect these facts.

Third: The organizational determinants as age, size ownership and global presence were identities by revising the banks website and annual reports, Table (2) shows the measurement of bank characteristics.

Table 4. The Items Measured by Using Other Tools Rather than Direct Revision

Dimension	Item	Tools used to measure the attributes
Navigation	Number of errors	http://validator.w3.org/ The Markup Validator is a free service from world wide web consortium (w3c) that allows users to check the validity of XHTML and HTML and other web document such as SGML or XML DTD. The Markup Validator system is a very important step for site usability and browser compatibility, which has a great effect on saving money and time and consequently improves the quality.
Accessibility	Size, speed	http://sitespeed.me/en/ Slow responsiveness website will discomfit and defeat users, sending them to other sites. However, faster website will keep the users more engaged rather than keeping them waiting to load images or scripts. Developers always wish to optimize their websites and reduce hosting costs and bandwidth and as a result rank higher in search engine results. The Site speed website is easy to use: Simply enter the URL for the specific page and then click the button, and the size and speed load time will appear in the end section of the Site speed website.
Content	The number of times the website was updated each year	www.archive.org There is growing awareness and knowledge among libraries, which ensures that historical records are available for all researchers. Backing up and archiving data is essential for website owners, and helps designers to better understand the movement in shaping websites in the past in order to create better ones in the future . Internet archive is a free service provided for the public in order to access collections of digitized materials. It is very easy to use, you only have to access the site archive.org and will notice the search box, in which you enter the link (e.g. www.yourwebsite.com) and then press enter on your keyboard. You will then notice the appearance of a new page, which is the archive of your website, from the entire time of its construction until two days prior to today's date.
Accessibility	Determining the number of internal and external links	https://smallseotools.com/website-links-count-checker/ Small See tools is a free service tools that allows users to check multiple issues such as page authority, link tracker, link analyzer tool, broken link checker, etc. Link count check is one of the free tools that can be used to identify the number of internal and external links; simply enter the exact web page that you want to analyze, then the result will be displayed on the screen. It is recommended for website owners to check the number of external links as a starting point to eliminating pages that may damage the reputation. This tool is particularly helpful if the website owner wants to exchange links to avoid purchasing unneeded advertising and to ensure quality. It can also be used to check the Google rank in order to determine if the Google page rank is fake or authentic and to check if there is a benefit from publishing a link or not.

Third phase: check the reliability of data

In order to evaluate the reliability, some specialists (Academic and bankers) from different countries such as Pakistan, Iraq, Italy and the United States of America were asked to review the collected facts. For example, the collected data on the Excel spread sheets related to each 50 bank's website was sent to a banker working in the Bank of America, he revised around ten bank's websites from the sample and made sure that the data summarized in Excel sheet is correct.

Fourth Phase: Data analysis

The quantitative evaluation method (QEM) was used to assess the bank websites. QEM is a capable technique used to evaluate the artefact quality (i.e. Miranda, Cortés & Barriuso, 2006; and Evan & King, 1999). The process of the quantitative evaluation method consists of categorizing, distinguishing the dimensions, recognizing weights, rating the components of dimensions, finally, scoring of aggregate quality. Since the sample size is small and the data is not normally distributed, the Kruskal Wallis H test was used to determine the significant difference between local and foreign banks in term of quality dimensions. In addition, Spearman correlation test was used to examine the relationship between age, size and global presence of the bank, and the quality dimensions. Again, this test is useful since the sample size is small and the data is not normally distributed.

FINDINGS AND RESULTS

Table (5) shows the results of Mann-Whitney U test for the differences between local and foreign banks in term of quality dimensions. It can be seen that, there is a statistical significant differences between local and foreign banks in accessibility, content and security dimensions (p-value of chi -square ≤ 0.05). In addition, the result shows that the quality of service encounters dimensions for foreign banks is better than local banks. Moreover, the results illustrate that foreign banks mean rank ranging between 32.07 to 22.15 for content dimension and functionality dimension. Whereas the functionality and content dimensions of local banks mean rank ranging between 28.35 to 19.91. The results showed that the quality of service encounters dimensions for the foreign banks is more significant than local banks. This result is consistent with some studies as Malhotra & Singh (2007), Zouari & Taktak (2014). Other studies have not supported these results as Hassan, Mohamad, Khaled & Bader (2009), Zu, Zhou, Zhu, & Yao, (2011). These findings support hypothesis (1).

The general hypothesis of this section is that different ownership of banks has an impact of the design of website, the foreign banks could have better experience in designing high quality website and vice versa. The results of this section were amazing; three quality dimensions were affected by the ownership structure of banks, these dimensions were accessibility, content and security. The question is still why do these factors are better ranked by foreign banks in comparison with local banks?. Is it related to better technical capabilities, or related to other factors?. Almost always, the number of foreign banks' customers is less than the number of local banks, accordingly, better accessibility is expected to the website. On the other hand, better content could be related to the diversity of foreign banks' customers, which requires more diverse content and different media adopted. However, the better security could be

Table 5. Mann-Whitney U test Results for the Impact of Ownership Structure on the Quality Dimensions

Quality Dimension	Mean Ranks of ownership		Mann-Whitney U Asymp.Sig (2-tailed)
	Local	Foreign	
Functionality	28.35	22.15	233.5 .134
Accessibility	21.11	30.65	192* .020
Navigation	25.48	25.52	310.00 .992
Content	19.91	32.07	159.500** .003
Customization	23.41	27.96	254 .271
Security	21.85	29.78	214* .049

* p- Value ≤ 0.05 ** p-value ≤ 0.01

related to wider scope of foreign banks' operations outside local borders, which requires more concern about developing more secure restricted websites. In addition, the most of foreign banks working on the Middle East region are western banks; these banks are almost leaders in launching e-services in comparison with local banks, so they have better experience in adopting more advanced security technologies.

Table (6) shows that there is a statistical significant relationship at the significance level ($\alpha \leq 0.05$) between global presence and the quality dimensions of customization and security. The results showed that no significant correlation between age of bank and the quality dimensions of internet banking service encounter. The findings support hypothesis (2) and reject hypothesis (3) and (4). The findings of this study showed that the age of bank does not affect the quality of internet banking websites. Some studies don't agree with this finding, for example, Malhotra & Singh (2007) suggested the younger banks are more likely to adapt this technology, and Acharya, Kagan & Rao Lingam (2008) argued that early adaptors of modern technologies may have more efficiency and competitive advantages.

The results also showed that the number of employees does not have a significant relationship with the quality dimensions. Some previous studies reached the same result as the study of Hassan, Mohammad, Khaled & Bader (2009) and Zu, Zhou, Zhu, & Yao (2011), while other studies have not support this result such as the study of Malhotra & Singh (2007). The findings of this study concluded that there is a significant positive relationship between the global presence of banks and the quality in term of customization and content, this result is in line with many researchers as Malhotra & Singh (2007), Schiavone, Meles, Verdoliva, & Del Giudice (2014) and Shneor (2012).

The result of this part is in line with the previous result of the impact of banks ownership. The global presence of banks means working outside the local borders, which requires more concern about content and security, the justification of this result is more global presence of banks requires content that is more diverse in order to satisfy the more diverse customers. In addition, the banks with global presence should have more experience in solving technical problems since it deals with customers that are more diverse and could be encountering the hacking and security issues more than banks working within national borders only.

Table 6. Results of Sperman Correlations Test for the Relationships between Service Encounter Quality and determinates

Quality Dimension		Age of Bank	Size of Bank	Global presence
Functionality	Correlation Coefficient Sig.(2-tailed)	-.079 .583	.090 .534	-.198 .169
Accessibility	Correlation Coefficient Sig.(2-tailed)	.191 .185	-.130 .370	.143 .321
Navigation	Correlation Coefficient Sig.(2-tailed)	-.054 .710	-.135 .350	.022 .879
Content	Correlation Coefficient Sig.(2-tailed)	.215 .134	-.253 .076	.265 .062

Security	Correlation Coefficient Sig.(2-tailed)	.180 .210	.132 .362	.388** .005

* p- Value ≤ 0.05 **p-value $\leq .01$

IMPLICATIONS AND FUTURE RESEARCH DIRECTIONS

This research provides better insight about the impact of organizational characteristics on the internet banking service encounter quality. If the banks will work outside their national borders regardless of their size and age should concern about the content, security and customization characteristics of the internet-banking website. This is required since the global presence requires from the bank to deal with more diverse customers, so more diverse content and customized websites is required to satisfy the customers. On the other hand, working outside local borders will increase the probability of banks to encounter more hackers and invading the websites security, so more concern about improving the security technologies is recommended. The local banks in the Arab Middle East region regardless of their size and age could benefit from the foreign banks' experience in designing the internet-banking website in term of security, content and customization.

The academics could benefit from the results of this study through better insight of e-banking practices and the organizational determinants at regional level. The most of available contribution is still country based, or a comparison between two countries, or limited number of countries. The primary limitation of this study is the scope and the size of its sample as well as other variables (i.e. market, environmental, regulatory etc.) which may effect on the decision of the banks to adopt internet banking. So it is recommended to conduct future researches by using larger sample size, and it is more beneficial to conduct a cross regions analysis.

CONCLUSION

This study is one of limited studies that explore the impact of organizational determinants on the internet banking service encounter quality. The aim of this chapter was to evaluate the impact of organizational determinants in term of ownership, age, size and global presence on the quality of internet banking service encounter quality in the Arab Middle East region. A sample of fifty banks from eleven countries was surveyed. Two questionnaires were used; one of them was directed to professionals to weight the

dimensions of quality. Another one was used to report the quality dimensions and bank's characteristics. Detailed analysis methodology called quantitative evaluation was adopted to weight and rate quality dimensions, further, Mann-Whitney U test and Sperman correlation coefficient were used. This study revealed that; there is a statistical significant difference in accessibility, content and security dimensions between foreign and local banks. Global presence has a significant impact on customization and security, but age and size of the bank doesn't have a significant relationship with quality of service encounter dimensions.

Entrepreneurship and SMEs

Entrepreneurship: Concept and Theoretical Framework

Jose Manuel Saiz-Alvarez

EGADE Business School, Tecnológico de Monterrey, Mexico, & Universidad Católica de Santiago de Guayaquil, Ecuador

INTRODUCTION

As entrepreneurship is an engine of innovation and job creation (Thornton & Yang, 2012), nations with high rates of entrepreneurial activity are those that are more developed economically, so that entrepreneurship is one of the essential elements to achieve sustainable economic growth and the generation of wealth and well-being. Entrepreneurs discover and exploit new business opportunities guided by intuition (Saiz-Alvarez, Coduras, & Cuervo-Arango, 2013), field studies, entrepreneurial spirit, and risk control to achieve GDP (Gross Domestic Product) growth, higher socioeconomic wealth (Saiz-Alvarez, Coduras, & Cuervo-Arango, 2014), and social change.

Contrary to Van Praag and Van Ophem (1995) and Murphy (1986), who affirm that entrepreneurship was first studied in Cantillon's *Essai sur la nature du commerce en général*, published posthumously in 1755, the concept of entrepreneur (in the sense of merchant) was first studied in Spain in the second book of Tomás de Mercado's *Tratos y contratos de mercaderes y tratantes discididos y determinados* [Deals and Contracts Applied to Certain Merchants and Traders], published in 1569, and reedited with a few tweaks in 1571, as *Suma de tratos y contratos* [Treaty on Deals and Contracts]. Regarding entrepreneurship, Tomás de Mercado approves the creation of new business and the importance of exchange trade to economic growth, only if they are consistent with the moral rules based on not taking advantage of others by using abusive prices and interest rates, or by conducting unfair agreements, both socially and economically (Saiz-Alvarez & García-Vaquero, 2017).

Given the impact of entrepreneurship in a firm, «contemporary economic theory recognizes entrepreneurship as an independent factor of production on a more-or-less equal footing with land, labor, and capital» (Hébert & Link, 1989, p. 40). The objective of this chapter is to describe the different theories entrepreneurship briefly, by including classical and new theories of entrepreneurship, both from economic, sociological, ecological, and psychological perspectives.

BACKGROUND

Entrepreneurship: Concept

Entrepreneurship is the process of identifying and developing economic, business and social opportunities (Shane & Venkatraman, 2000) through the efforts of individuals and organizations (Thornton & Yang, 2012), and it can be analyzed generating a multidimensional perspective (Bula, 2012). Entrepreneurship is the act of innovation involving endowing existing resources with new wealth-producing capacity

DOI: 10.4018/978-1-7998-3473-1.ch096

(Drucker, 1985), as the nature of the decision-making context with entrepreneurs' decisions (Alvarez & Barney, 2005). As a result, and applying a fundamentally personal perspective (Baum et al, 2007), «the entrepreneur is someone who is specialized in taking responsibility for and making judgmental decisions that affect the location, form, and the use of goods, resources or institutions» (Hébert & Link, 1989, p. 213).

Successful entrepreneurs must identify business opportunities (Stevenson & Jarillo, 1990; Barringer & Ireland, 2006; Timmons, 1999; Mariotti & Glackin, 2010) to create wealth, be able of choosing and managing entrepreneurial careers (Haynie & Shepherd, 2011), and be capable of acting entrepreneurially (McMullen & Shepherd, 2006; Shepherd & Patzelt, 2011) by being adapted to the market given their expertise (Velilla, Molina, & Ortega, 2018) and their capacity of resilience to failure. As a result, entrepreneurs are the business core of a company, especially in newly-born firms, where they act as inventors, investors, accountants, facilitators, organizational change specialists, leaders, technologists, and marketing specialists (Frese & Gielnik, 2014). Given the above definitions, entrepreneurship is defined as the type of business strategy focused on the creation of jobs, social wealth, and profit by optimizing the use of productive and commercial resources for economic growth (Saiz-Alvarez & García-Vaquero, 2017).

Entrepreneurship is associated with the «pursuit of the generation of value, through the creation or expansion of economic activity, by identifying and exploiting new products, processes or markets» (Ahmad & Seymour, 2008, p. 9). In this sense, Lumpkin and Dess (1996) assure that the essential act of entrepreneurship is launching startups and corporate venturing accomplished by entering into new or mature markets with new or existing goods and services. Entrepreneurial activities guided by some theories of entrepreneurship that will be analyzed in the next section.

ECONOMIC-BASED THEORIES OF ENTREPRENEURSHIP

The Neoclassical School

The combination of psychological and managerial traits in entrepreneurs is fundamental to understand entrepreneurial behavior. In this sense, entrepreneurial individualism in competitive markets and the consideration for market participants' knowledge determine entrepreneurship (Egger, 2008). In this sense, Hébert and Link (1989), cited by Audretsch (2003), have identified three distinct intellectual traditions in the development of the entrepreneurship contemporary literature: [1] the German Tradition, based on von Thünen (2015[1875]) and Schumpeter (1997[1911]), that has the most significant impact on the contemporary entrepreneurship literature; [2] the Chicago Tradition, rooted on Knight (1921) and Schultz (1980), and [3] the Austrian Tradition, based on von Mises (1949), Kirzner (1979), and Shackle (1968). We can add emerging intellectual traditions formed by Latin American, Spanish and Portuguese researchers (the Iberoamerican Tradition), given the socioeconomic peculiarities of these countries that have been barely studied so far in the economic literature on this issue.

In his classic treatise, *Theorie der wirtschaftlichen Entwicklung. Eine Untersuchung über Unternehmergewinn, Kapital, Kredit, Zins und den Konjunkturzyklus* [Theory of Economic Development. A Study of Entrepreneurial Profit, Capital, Credit, Interest Rate, and the Business Cycle], Schumpeter (1997[1911]) proposes a theory of creative destruction, where new firms equipped with the entrepreneurial spirit displace less innovative incumbents, leading to economic growth, as a «function of entrepreneurs is to reform or revolutionize the pattern of production by exploiting an invention, or more generally, an untried technological possibility for producing a new commodity or producing an old one in a new way»

(Schumpeter, 1977[1942], p. 13). As a result, Schumpeter (1934) defines entrepreneurs by focusing on adopting innovation and new business strategies that can take several forms: [1] the introduction of new methods of production to increase productivity, efficiency, and EBITDA (Earnings Before Interests, Taxes, Depreciation, and Amortization); [2] the introduction of new goods or quality thereof; [3] the opening of new markets; [4] the conquest of new sources of supply of new materials or semi-elaborated products; and [5] the entry to new market niches or sectors. In short, entrepreneurs identify opportunities, assemble essential resources, implement a practical action plan, and harvest the reward in a timely, flexible way (Sahlman & Stevenson, 1991).

Regarding the Chicago and Austrian traditions, entrepreneurs attempt to predict and act upon change within dynamic and uncertain markets (Knight, 1921). According to both cultures, free market conditions determine the competition in global markets, so public intervention is harmful, as it detracts economic resources to private firms (crowding-out effects). As a result, entrepreneurs are immune from control of rational bureaucratic knowledge (Weber, 1947), so they can be defined as the professionals who discover new business opportunities, after having taken into account commercial and financial risks, and the subsequent creation of new economic activity, often through the establishment of new business organizations (Reynolds, 2005).

For this School, entrepreneurs must compete in a globalized business world, by thinking globally and acting locally (“glocalization”). Therefore, entrepreneurs must keep labor costs in line with productivity and must achieve a steady increase in production to satisfy existing market niches and enter into new markets. If that sustained growth is not performed, there is a risk of business stagnation, which is detrimental to the company’s stakeholders.

Entrepreneurs, as coordinators and arbitrageurs, as well as the chief judgment-based agent of production in the economy (Hébert & Link, 1988, cited by Bula, 2012), are always speculators, as they deal with the uncertain conditions of the future, so it is vital for them to have success in the correctness of their anticipation of unpredictable events (Von Mises, 1949).

In a globalized socioeconomic world, entrepreneurs create social and economic wealth by bringing together unique packages of resources to exploit marketplace opportunities (Ireland, Hitt, & Sirmon, 2003) guided by opportunity recognition (Gaglio & Katz, 2001; Shanke & Venkataraman, 2000; Kirzner, 1979), and by creating a previously-unperceived opportunity for profit (Von Mises, 1949). In short, and as Grebel, Pyka, and Hanusch (2001) gather from Schumpeter and the Neo-Schumpeterian School, «no entrepreneur—no innovation — no dynamics — no evolution» (p. 7).

The New Keynesian School

Entrepreneurship is marginal in the new Keynesian school, as labor markets only deal with the development of efficiency wage models. Despite this issue, the implementation of public policies to support private entrepreneurship generates crowding-in effects, although public spending is increased, so new entrepreneurs are created.

By combining macroeconomic government spending data with individual-level entrepreneurship data, Islam (2015) finds a positive relationship between increasing the share of social and public goods at the cost of private subsidies and entrepreneurship, while confirming a negative correlation between total government consumption and entrepreneurial activity.

In our globalized world, informal ventures are increasingly important and are influenced by economic and political factors affecting entrepreneurship. In this sense, Autio and Fu (2015) study the influence of economic and political institutions on the prevalence rate of formal and informal entrepreneurship

across 18 countries in the Asia-Pacific region during the period 2001-2010 and find that the quality of institutions influences on both formal and informal entrepreneurship. Higher quality of economic and political institutions doubles the rates of formal entrepreneurship and halves the rates of informal entrepreneurship. Moreover, both economic and political institutions have a complementary effect on driving entry into formal entrepreneurship, whereas only direct effects are observed for informal entry.

Entrepreneurs for New Keynesian economies are benefited from public expense and investment. In effect, government's Keynesian functions stimulate demand for goods and services through purchases and income redistribution; while government's Schumpeterian economic policy lowers the cost of innovation through regulatory requirements, R&D subsidies and innovation, and the acquisitions of expensive and new technology. These two economic-based Schools of thought are complemented with psychological-based Schools, as a mixture of both economic and psychological thought forms entrepreneurship.

The Ordoliberalism School

Born in the University of Freiburg (Germany) as a substitute to *laissez-faire* liberalism and collective forms of political economy. The Ordoliberalism, mainly developed in Germany and Spain (Ban, 2012) during the 1940s onwards, is based on a mixture formed by a sort of Bismarckian-based paternalism, liberalism, and the social-democratic ideas of social justice to achieve both economic and social stability. This School of thought argues for active private-public collaboration, given that public intervention generates crowding-in effects that compensate for the widely discussed crowding-out effects (Saiz-Alvarez, 2018, p. 16)

For the Ordoliberalist School of Thought, the entrepreneur is fundamentally a political practice; that is, the healthy state is the political form of market liberty (Bonefeld, 2011). The free economy presupposes the exercise of persuasive state authority, and that economic freedom is a practice of liberal governance (Bonefeld, 2012). Social individuals as self-responsible entrepreneurs who more than just complying with the rules of the game do so willingly based on their initiative. As a result, Ordoliberalism "should not... be identified with *laissez-faire*, but rather with permanent vigilance, activity, and intervention." (Foucault, 2010, p. 132) For entrepreneurs to be fostered and protected, at the level of both the individual and the firm (Storey, 2017). Consequently, cartels and monopolies must be legally prohibited, while entrepreneurs must be obliged to take responsibility for their economic welfare through the market (Dulien & Guerot, 2012, p. 2).

NON-ECONOMIC-FOCUSED APPROACHES TO ENTREPRENEURSHIP

Sociology and Entrepreneurship

The dominant School of Thought in Sociology related to entrepreneurship is the supply-side perspective, which focuses on the individual traits of entrepreneurs, while the demand-side perspective has focused on the context in which entrepreneurship occurs (Thornton, 1999) to determine the economic, political and social environment that influence people's willingness and ability to undertake entrepreneurial activities (Gnyawali & Fogel, 1994). Regarding the supply-side perspective, the presence of congenial cultural attributes easing entrepreneurship are formed by social class and ethnic groups more prone to entrepreneurship (Aldrich & Waldinger, 1990; Shane, 1993; and Shapero & Sokol, 1982) daunting environmental constraints (Agboli & Ukaegbu, 2006) mainly defined by influences of firms and markets

(Thornton, 1999); public policies (Dobbin & Dowd, (1997); regulations and policies (Baumol, 1990), physical infrastructure (Agboli & Ukaegbu, 2006). Special topics related to the socioeconomic aspects of entrepreneurship are immigrant entrepreneurship (Coduras, Saiz-Alvarez, & Cuervo-Arango, 2013), and the mechanisms of intergenerational transmission of self-employment (Sørensen, 2007).

Psychological-based Schools

While the study of entrepreneurship began for Economics and Managerial Sciences in the second half of the XVI century, the first psychological studies about this topic started with the seminal works of Schumpeter (1934), and three decades later, McClelland (1965, 1967), Rotter (1966), and Atkinson (1966). These authors focused on explaining how individual and social motivation is one of the most important psychological factors to teach entrepreneurship and discover that imagination, power distance, and willingness for taking risks are critical factors for success. When the possibility of achievement gets higher, the entrepreneurial propensity rate increases (Kalkan & Kaygusuz, 2012).

Self-efficacy and the need for achievement are highly associated with entrepreneurship (Frese and Gielnik, 2014). From a psychological perspective, entrepreneurship has three phases (prelaunch or opportunity-necessity identification, launch, and postlaunch)(Baron, 2007) where the influence of the individual entrepreneur tends to diminish as well as his or her company grows (Hambrick, 2007).

The mentality of entrepreneurs differs, as they are driven by *entrepreneurial alertness* (Kirzner, 1979) defined as a unique set of perceptual and cognitive processing skills directed to opportunity recognition processes. As a result, and given this entrepreneurial alertness, only the most risk-lovers tend to be successful while managing their businesses, as «the entrepreneur always searches for change, responds to it, and exploits it as an opportunity» (Drucker, 1985, p. 25).

Regarding entrepreneurship, five Schools of thought can be distinguished, as follows: [1] *Functionalism*, where theorists try to explain ideas, the learning process, instincts, and decisions merely describing what entrepreneurs do, without asking how they do it.

In this sense, is of interest to link resilience and functionalism, as rule-governed behavior turns people insensitive to contingencies, so a higher capacity of resistance is achieved; [2] *Behaviorism*, rooted on Functionalism, is focused on both human and animal behaviors, so it analyzes the reasons why entrepreneurs act; [3] *Gestalt*, where human mind interprets data through several norms, laws, and organizational principles, so partial information can be completed. This completeness is necessary to make decisions with imperfect or asymmetric information, as is standard in the daily operations done by companies; [4] *Humanistic Psychology*, based on human motivation and satisfaction of needs, has a direct influence on entrepreneurs, as they want to be happy by achieving corporate goals, and [5] *Cognitivism*, as well as Behaviorism, studies the mind through scientific experimentation, but differs from Behaviorism by accepting that psychologists can research and understand the inner workings of mind and mental processes, so psychoanalysis is rejected given its subjectivity.

These psychological theories applied to entrepreneurship complement economic and managerial theories on entrepreneurship, to have an overview of the entrepreneurial behavior. Entrepreneurs with better growth prospects have a high need for power and independence (Duchéneau and Orhan, 1998), as the need for achievement and competition is positively correlated with the result of the company. Moreover, entrepreneurs have a greater need for success (Box, White, & Barr, 1993).

The influence of psychological aspects on entrepreneurs is also seen in the modern theories of entrepreneurship that will be analyzed in the next paragraph.

NEW APPROACHES OF ENTREPRENEURSHIP

The Theory of Effectuation

According to this approach, entrepreneurs make decisions and perform actions only when they identify the best way to assess the resources available focused on achieving their business goals, while continuously balancing their goals with the resources they have. As a result, the four principles of effectuation are (1) Entrepreneurs create solutions with the resources really available (*Bird-in-Hand*); (2) Mistakes, and surprises are inevitable and can be used to look for new opportunities (*the Lemonade Principle*); (3) Entrepreneurs should only invest as much as they are willing to lose (*Affordable Loss*); and (4) New partnerships can bring the project new funds and new directions (*Crazy Quilt*)(Sarasvathy, 2001)

The Feedback Loop Theory

Developed by Ries (2011), decision-making used by entrepreneurs is guided by turning entrepreneurial ideas into developing a minimum viable product, which is then tested on potential customers, partners,

and other stakeholders in a constant feedback loop formed by three iterative stages: (1) to build a product; (2) to measure data created by messages developed by stakeholders, primarily customers and partners, and (3) to learn ideas to be applied into the firm.

The Jack-of-all-trades Theory

Theoretically developed by Lazear (2005), and mathematically by Kaiser (2012), entrepreneurs' primary task is to organize professional teams ("generalists"/"specialists") by combining capital. In this respect, Saiz-Alvarez (2012) affirms that capital is composed of intellectual capital (sum of human capital, relational capital, and structural capital), physical capital and ideas to innovate with the final goal of creating products and services to actual and prospective clients. According to this entrepreneurial theory, only generalists ("jacks-of-all-trades") become entrepreneurs, as they assemble production factors, and have knowledge, skills and working abilities in a large number of areas, especially when entrepreneurs are individuals. The reason for this behavior is that entrepreneurs need to manage different people and tasks, so they must be sufficiently well versed in diverse fields by the positive affecting accumulation of various skills (Silva, 2007). Generalists "typically have a more varied labor market experience, and that varied work experience is associated with the lower household income" (Astebro and Thompson, 2009, p. 1). As a result, and according to Kaiser (2012): [1] individuals with more balanced skill sets are more likely to become entrepreneurs; [2] the supply of generalists entrepreneurs is smaller for production processes, as they require a large number of independent skills; and [3] generalists entrepreneurs have, on average, a more balanced human capital strategy than specialists. Behind this theory is that entrepreneurs must have enough knowledge to put together the many ingredients needed for survival and business success, while paid employees must be specialists (Wagner, 2003).

The Mezzanine Theory

Formed by a financial and commercial mezzanine, it consists of a technique that combines two or more investment instruments, called tranches, within a facility sold as a single entity to investors. A simple mezzanine facility contains: (a) subordinated debt; (b) a tranche where the investor receives a share of the firm's earnings or profits and; (c) an equity-related tranche ("equity kicker") in which an investor receives a payment related to the company's share price. As a result, a commercial mezzanine investment usually takes the legal form of a private investment limited partnership organized by professionals in the management of mezzanine investments which identify good companies (20-30 companies on average) to invest and monitor their performance, to participate in their boards, and to liquidate the fund at the end of its mandate (usually 7-10 years). These professionals receive fees (around 2%) for all assets under management, as well as a share of the profits of the investment. The exact mix of devices in a specific firm is generally tailored to suit the needs of the firm and the investors.

The O-Ring Theory

Seminally developed by Kremer (1993), and theoretically by Fabel (2004), the O-Ring Theory deals with abilities, and product, task, and service quality in firms, as various individuals with different capacities supply different talents and skills. Teamwork is essential in this theory, as if a group member ("specialists") fails to fulfill the task, the entire project will tend to fail. The abler of the team, the more per capita capital is used, so it is preferable to limit the size of the group, as more per capita capital must be used.

The extension of this theory applied to economic development and entrepreneurship is the concept of O-ring jobs (Jones, 2013) defined by being strategically complementary in terms of skills.

The Theory of Resources and Capabilities

This theory can be seen as an “inside-out” process of strategy formulation, as the entrepreneur looks at what resources the firm possesses to assess their potential for value generation defined in a business strategy to capture the maximum value sustainably. These financial, physical, human, technological, reputational, and organizational *resources* input to be taken into account for the production process, while *capabilities*, defined as the capacity for a team of resources to perform some task or activity, constitute the primary source of the firm’s competitive advantage.

One of the keys to having success when applying this theory into practice is to efficiently utilize *routines*, defined as those regular and predictable patterns of activity which are made up of a sequence of coordinated and repeated (*learning-by-doing*) actions done by individuals. As a result, economies of experience are created and sustainable and activities guided by appropriability.

Figure 1. Branches of the Capability Lifecycle

Source: Elaborated from Helfat and Peteraf (2003).

Achieving sustainability is fundamental to the firm’s reputation and good economic results in the long term. The four main elements for the sustainability derived from resources are [1] *durability*, defined as the rate at which resources depreciate or become obsolete; [2] *replicability* when entrepreneurs acquire resources inside the organization. The more complex the organizational routines are, the more difficult it will be to replicate them (Grant, 1991); [3] *transparency*, as incomplete information creates inefficiency-based problems; and [4] *transferability* when rivals can easily acquire resources and capabilities, so leading positions can be in danger.

Successful firms must hire the best human resources, as well as renew the level of capacity per unit of activity and to continually invest if they want to be leaders in their sectors. Complex organizational skills pose a significant barrier for other firms to enter the market, and especially when economies of experience are well developed.

The Theory of the Optimal Triangle

Companies are having a high level of business growth and motivation, influence positively on the formation of new business ideas. It is, therefore, essential that emotional characteristics close to the ability to work and enthusiasm must be developed to take forward the company. Without passion, mainly in start-ups, it is impossible for firms to survive in the global market.

Business success is positively related to the level of training, participation in previous projects, business experience, and the number of founders. These factors, however, can change by other endogenous variables, such as debt, product prices, stakeholders' attitudes, and investments, purchases, rotation sales, and wages, and exogenous factors, such as energy prices, external shocks, and country risk, among others.

Figure 2. Optimal Situation and Business Success

Source: own elaboration

We propose to summarize these variables in three key terms: entrepreneur, business ideas, and capital, as shown in Figure 2. Successful entrepreneurs are at the top of the triangle, because they support entrepreneurs, as they are fueled by intellectual (as the sum of human, relational and structural capital), physical, and financial capital. The combination of entrepreneurial resources and capacities, working experience by learning-by-doing, formation, and capital determine the optimal situation for the company. As seen in figure 2, this point is between the vertices “entrepreneur” and “capital,” as they are fundamental to have business success.

DISCUSSION

Entrepreneurship is one of the key variables that differentiate countries, since, with a high entrepreneurial spirit, the creation of wealth is more significant, as well as the formation of quality employment. As a

result, thanks to entrepreneurship, the growth of companies is strengthened by intra-entrepreneurs, as well as by countries with entrepreneurs located in different sectors and industries.

When a nation does not have entrepreneurs, it is the State that has to assume the creation of employment and wealth, which leads to a situation of monopsony that is not desirable for the economic stability of the countries. Monopsony leads to productive inefficiencies, as well as to inevitable technical obsolescence that can be made structural over time. For this reason, the generation of private entrepreneurs that complements, and even substitutes in the most neoliberal countries, the dynamizing process generated by the Public Administrations is better for the economy. Public interventionism generator of crowding-in effects that benefits the private sector. Therefore, the ideal situation is the combination of a public and private initiative directed jointly to the creation and development of entrepreneurs.

Given the importance of entrepreneurship in countries as a generator of employment and wealth, there is a triple economic, social, and psychological vision in entrepreneurship. Regarding the economic view, the neoclassical contributions, led by Schumpeter and the tradition of the Austrian and Chicago schools, which focus on the entrepreneur as an individual with success and social recognition, as well as creator of wealth stand out. However, this neoclassical model is valid only from an entrepreneurial vision when entrepreneurs have the financial resources necessary to undertake, a situation that does not always occur in developing countries. For this reason, the impulse in the developing countries must also come from the State, in collaboration with the private sector. Hence, both a Keynesian and Ordoliberalist vision is more realistic for these countries.

In contrast to the economic vision of entrepreneurship, characterized by its diversity, there is more excellent uniformity in the application in countries of the psychological and sociological perceptions of entrepreneurship. In other words, the human being has the same psychological-based entrepreneurial characteristics in different countries which leads us to conclude that the main differences in the quality and quantity of entrepreneurs are mainly due to financial aspects related to entrepreneurship rather than the psychological characteristics of entrepreneurs who seem to be guided by a typical pattern throughout the world.

Given the severe problems of lack of economic development in developing countries, psychological theories include the so-called 'Humanistic Psychology' which advocates directing all the entrepreneurial efforts towards the satisfaction of corporate objectives. From a psychological perspective, entrepreneurs are being defined by having a spirit of improvement, a social conscience, and a desire for self-improvement to leave a legacy for the new generations. Many times in this life, entrepreneurs are happier giving than merely earning money due to the growing social impact that entrepreneurs have on society.

Entrepreneurs are the primary judgment-based agent of production, distribution, and selling of goods and services in the market, so they are speculators to earn money. The only exception of this fact is when the State does it to create social wealth and employment. As a result, this type of public-private collaboration strengthens and accelerates the creation of new jobs and wealth in the economy, which directly affects the generation of higher levels of economic and social well-being.

The new approaches of entrepreneurship enrich the vision that exists about entrepreneurship, mainly following economic reasoning. The ideas that emanate from these theories invite the creation of incubators and accelerators of companies under quadruple helix schemes (HEIs, companies, state, and NGOs) to increase and democratize the social impact of organizations. One of the characteristics of the developing countries is the weak social conscience of the business organizations, which leads them to hardly carry out (if they do) corporate social responsibility. Mainly in Europe, this social awareness of companies is much stronger than in other continents, which leads to an increase in the level of socioeconomic welfare

of the population. Levels of well-being strengthened by a robust public-private collaboration that creates positive externalities for both the company and society.

The creation of quadruple helix models, mainly in developing countries, can contribute to the structural transformation of these societies towards higher levels of wealth and socioeconomic well-being. The creation of wealth must be done among all economic agents so that the middle class guarantees the results obtained in terms of welfare. In this sense, everything achieved in the current generations will have a particularly positive impact on the new generations and those that have to come. For that reason, it is the responsibility of the current generations to leave a better world for the future ones, and in this sense, the entrepreneurial spirit has a fundamental role in fulfilling to achieve it.

CONCLUSION

Based on Information and Communication Technologies (ICTs), entrepreneurship can be classified as: [1] *Intraentrepreneurship* or *Corporate venturing* (Sharma & Chrisman, 1999), defined by the type of entrepreneurship focused on fast tracking product development to take advantage of new business opportunities or to assess feasibility of new processes or designs; [2] *Traditional entrepreneurship*, that according to Brunet and Alarcón (2004), can be classified as: [a] *Novice entrepreneurs*, when they manage their first firm; [b] *Habitual entrepreneurs*, that are classified as *serial entrepreneurs*, when they sell their original ventures to buy and develop new ones, and [c] *Portfolio entrepreneurs*, when they do not sell their innovative investments and buy others, so a cluster is created; [3] *Solidarity Entrepreneurship* (Saiz-Alvarez, 2015), where firms are guided by human values based on solidarity and not for profit, and [4] *Social Entrepreneurship*, mainly formed by cooperatives, whose aim is to maximize the impact of the company on the population searching for social wealth. In this sense, and after having analyzed data from 106,484 individuals in 26 nations, Stephan, Uhlaner, and Stride (2015) confirm joint effects on social entrepreneurship of formal regulatory (government activism), informal cognitive (post-materialist cultural values), and informal normative institutions, through socially supportive cultural norms, or weak-tie social capital. When entrepreneurs are focused on social entrepreneurship is possible to achieve social change, especially in developing countries defined by social inequalities and the generation of stable social groups characterized by poverty.

FUTURE RESEARCH DIRECTIONS

As future lines of research, the following ones may be indicated: a) Women Entrepreneurship, since women are having a growing role in entrepreneurship, especially in developing countries. The fact that has not yet been studied in depth; b) Social and Solidarity-based Entrepreneurship, because solidarity and the social economy are gaining strength in those countries where the state has fallen and does not efficiently perform its obligations to improve the lives of its citizens. This type of solidarity economy is growing very actively in Latin America and the Caribbean; c) ICTs, Business Incubators, and Accelerators, especially to form quadruple helix models where incubators and accelerators are linked to HEIs, public administrations, companies and NGOs; d) Entrepreneurship in HEIs (Higher Education Institutions), to analyze the entrepreneurial initiative of the students that are the future of the nations. The greater the number of entrepreneurs, the higher the level of present and future wealth, and the higher economic growth and economic and social well-being; e) Entrepreneurship, Poverty, and Sustainable Economic

Growth, because entrepreneurship is one of the mechanisms to fight poverty, especially in third world countries where the State is absent in support of society; and f) Entrepreneurship and Leadership, due to the importance of the spirit of leadership in the creation of companies. A leadership that goes from individual to countries, as happens with the First World.

ACKNOWLEDGMENT

I would like to thank the shared funding received from EGADE Business School-Tecnologico de Monterrey (Mexico) and CONACYT (National Council of Science and Technology) of Mexico to carry out this work.

KEY TERMS AND DEFINITIONS

Capability: Capacity for a team of resources to perform some task or activity, which constitutes the primary source of the firm’s competitive advantage.

Entrepreneur: Individual who starts a new business or adopt new business strategies in existing organizations.

Entrepreneurship: Business strategy focused on the creation of jobs, social wealth, and profit by optimizing the use of productive and commercial resources.

Glocalization: Term created by the combination of «global» (think global) and «local» (act local) widely used in academia and global businesses.

Intellectual Capital: It is formed by the combination of human, structural, and relational capital.

Resilience: It is defined as an individual resistance to failure, usually in business.

Resource: Inputs to be taken into account for the production and commercial processes.

Social Entrepreneurship

INTRODUCTION

Social entrepreneurship is commonly used to describe entrepreneurial activities that serve a social and/or environmental cause and that reinvest a large part of their surpluses in support of that mission. According to Dees & Anderson (2006), social entrepreneurs are considered as entrepreneurs with a social mission. Although this definition, and its boundaries remain unclear, social entrepreneurs focus on achieving both economic efficiency and creating social value (Martin & Osberg, 2015).

Although interest in social entrepreneurship seems to be recent, the first works on this topic were done as early as the 1960s and became widespread around the 1980s, mainly around the nonprofit sector (Guo & Bielefeld, 2014). The concept itself seems to have been developed in the 1990s in Europe, with the development of social cooperatives, and interest has grown exponentially, particularly after the 2008 financial crisis that hit the USA. Hence, the main objective of this chapter is to conceptualize social entrepreneurship, together with its importance in terms of its contribution to social value creation and its relation to innovation and sustainability.

The chapter begins by conceptualizing social entrepreneurship and the characteristics of a social entrepreneur from different points of view. Secondly, the definitions that have arisen from Harvard Business School, specifically the *Social Enterprise School*, which focuses on the organizations and considers the development of market based solutions to social problems, including profit and non-profit activities; and the *Social Innovation School*, which focuses on the role of the social entrepreneur and the way that they produce social value by shifting resources into areas where they are needed (Dees & Anderson, 2006, p. 41), are analyzed.

Finally, a social entrepreneurial ecosystem is proposed, highlighting the links between social entrepreneurship, sustainability and social innovation together with the trends, issues and challenges that have arisen in recent years. Future research directions include analyzing the influence of the socio-political, environmental and economic ecosystem on the development of social entrepreneurship in each country, at a local, regional and national level, analyzing the financial and legal difficulties faced by entrepreneurs and the reasons why social entrepreneurship is still highly gendered.

BACKGROUND

Social entrepreneurship is defined by the creation of social value, rather than personal wealth (Dees, 1998). According to the literature, its emergence began in Europe with the development of social cooperatives in Italy (1995), social purpose companies in Belgium (1995), social solidarity cooperatives
DOI: 10.4018/978-1-7998-3473-1.ch097

in Portugal (1998), and cooperatives with a collective interest in France (2001). In the US, since the economic and financial crisis of 2008, there has been an increased interest in social entrepreneurship and social innovation given the dissatisfaction generated by other forms of programs, including the lack of community participation and their environmental, social and economic impacts (Moulaert, MacCallum, Mehmood & Hamdouch, 2013). Therefore, the concept itself is a reasonably new one and the area can certainly be described as an “emerging field.”

According to Brock and Ashoka (2008, cited in Guo & Bielefeld, 2014) the first social entrepreneurship class was taught at Harvard University in the mid 1990s, followed by other universities in the USA (Les repères de l'AVISE, 2007); the first European course was at the University of Geneva in Switzerland in 2003.

This developments led to a rapid rise in social orientated enterprises, together with improvements in the legal frameworks (at a national and international level); likewise, companies and devices that help social entrepreneurship emerged (such as Ashoka foundation, Skoll Foundation, Schwab Foundation and Yunus Center, Socialab, amongst others) and there was an increase in audience related to social projects (including the media, academic institutions and different economic actors) (Fournier, 2011).

FOCUS OF THE ARTICLE

Definition of Social Entrepreneurship

The concept of social entrepreneurship has its foundations in the social problems faced by communities, given the unmet social needs (i.e. due to government, market and contract failure), the importance of earned income, together with the opportunities and challenges that emerge from the external environment including demographic, technological and environmental (Thompson, Alvy & Lees, 2000; Guo & Bielefeld, 2014). Therefore, social entrepreneurship often develops at the intersection between civil-society, the state, and the market. Fowler (2000, p. 638) points out that throughout history, governments have focused on reducing “poverty, inequity, insecurity and injustice,” but their solutions have not been accurate, as this are still predominant features of the current socio-economic system; thus, a big difference has been made by social entrepreneurs none reliance on the “traditional” framework employed by the official aid system and their willingness to develop solutions to those “old problems.” This phenomenon transcends the separate domains of entrepreneurial studies, social movements, and nonprofit management (Dacin, Dacin, & Matear, 2010). Social entrepreneurs are people looking towards change, but a modern kind of change that takes its inspiration from a determined focus on solutions: “Mission related impact becomes the central criterion, not wealth creation” (Dees, 1998, p. 3).

According to Dacin *et al.*, (2010, p. 37) “social entrepreneurship depends on the context in which established types of entrepreneurs operate.” Currently, social entrepreneurship literature is a field of interest that crosses academic disciplines and challenges traditional assumptions of economic and business development. As far as conceptualizing it, Dart (2004) refers to it as an ability to leverage resources that address social problems, although there is little consensus beyond this generalization. Zahra, Gedajlovic, Neubaum, & Shulman (2009) mention the importance of activities aimed towards social responsibility or social innovation (Bornstein, 2004) and Emerson & Twersky (1996) refer to it as sustainable ventures that generate social value. These definitions also take into account the entrepreneurial ecosystem, which includes start-ups, incubators and all the business functions relating to business development, finance

and accounting, market analysis, communications, human resources, research and development, amongst other areas.

Tschirhart & Bielefeld (2012, p. 36) mention that social entrepreneurship is defined as the pursuit of social objectives with innovative methods, through the creation of products, services, organizations and practices that yield and sustain social benefits. Hence, social entrepreneurs play an important role as change agents in the social sector, adopting a mission to create and sustain social value by recognizing new opportunities and engaging in continuous innovation processes. This is done by making an appropriate use of social capital, which is considered the single strongest predictor of a successful social entrepreneurship, together with their ability to engage in resource mobilization (financial, social, environmental) (Tent, 2015).

Authors such as Hoogendoorn, Pennings & Thurik (2009) cluster the different perspectives of social entrepreneurship along epistemological dimensions in different schools of thought, namely; the School of Social Enterprise which concentrates on organizations and how they deal with funds, business models and strategies; and the School of Social innovation which centers on the development of innovative ideas to enable social transformation (Cano, Sanjuán & Fernández, 2015). However, it is also important to mention that the boundaries between these schools are blurred and generalizations should be made in a cautious manner.

Following Dees (2017, p. 38) the definition of social entrepreneurship “combines an emphasis on discipline and accountability with the notions of value creation taken from Say, innovation and change agents from Schumpeter, pursuit of opportunity from Drucker, and resourcefulness from Stevenson. In brief, this definition can be stated as follows: Social entrepreneurs play the role of change agents in the social sector, by: Adopting a mission to create and sustain social value (not just private value), recognizing and relentlessly pursuing new opportunities to serve that mission, engaging in a process of continuous innovation, adaptation, and learning, acting boldly without being limited by resources currently in hand, and exhibiting a heightened sense of accountability to the constituencies served and for the outcomes created.”

Table 1. Differences between social and traditional entrepreneurship

Categories	Social Entrepreneurship	Traditional Entrepreneurship
Impact	Social impact	Economic impact
Type of value	Create social value	Create economic value
Purpose	Create shared value with social purpose	Create value with profit purpose
Opportunity recognition	Recognize opportunities to improve social and environmental problems	Recognizes opportunities to create business
Governance	Is governed, in part, by social and environmental factors	Is governed by market concerns
Funding	Funded through subsidies, volunteering, donation, international cooperation	Funded through private capital and commercial funding
Accountability	Socially responsible in front of vulnerable and excluded communities	Corporate social responsibility in front of stakeholders
Focus	Tackle social problems	Earn profit

Sources: Literature review done by authors

Finally, according to Porter & Kramer (2011) social entrepreneurship equates to creating shared value, by reconsidering capitalism and unleashing a wave of innovation and growth. For Light (2008) the four main components of social entrepreneurship are the *Entrepreneur*, referring to the individual, the *Idea* that is considered as the mean by which transformations might occur, the *Opportunity* and the *Organization* that backs up the individual or group. Therefore, companies must realign themselves with society, in such a way that they can improve social conditions through social responsibility, in order to help marginalized communities who suffer the debilitating problems of poverty, inequity, insecurity and injustice, among others. Table 1 highlights the differences between social and traditional entrepreneurship.

Characteristics of a Social Entrepreneur

The qualities that characterize social entrepreneurs have been thoroughly studied by a variety of researchers including Bolton & Thompson (2005), Zhao & Seibert, (2006), Carsrud & Brannback (2009), Ernst (2012), Heinrichs & Sascha (2013) and variolus organizations. The Skoll Foundation, for example, states that social entrepreneurs focus on improving systems, inventing new approaches and creating sustainable solutions to change society for the better. The Schwab Foundation defines a social entrepreneur as a leader who combines innovation, resourcefulness and opportunities. Whilst, the Ashoka foundation defines social entrepreneurs as individuals with the vision and inexhaustible determination to transform an entire system, communities, societies, and the world (Light, 2005)

Light (2009, p. 5) highlights qualities centered on “issues of motivation, the ability to recognize opportunities and enact change through inspirational leadership skills, and/or the ability to gather necessary resources.” Hence, social entrepreneurs are considered “as one species in the genus entrepreneur with a social mission” (Dees, 1998, p. 2).

Social entrepreneurs have the capacity to innovate, to come up with and mobilize ideas and to focus on attainment of resources. Such people are creative, passionate and imaginative and they possess mental strength. According to Guo & Bielefeld (2014), there are four common characteristics of social entrepreneurs, which include having a balanced judgment in terms of being able to serve both the social mission and the financial needs of the organization in order to make it sustainable; being opportunistic, so that they are able to take advantage of opportunities; being virtuous by acting in an integer, compassionate and inclusive manner; and having the ability to endure risks and making accurate decisions.

Friedman (2005) stated that a social entrepreneur is “someone who burns with desire to make a positive social impact on the world, but believes that the best way of doing it is, as the saying goes, not by giving poor people a fish and feeding them for a day, but by teaching them to fish, in hopes of feeding them for a lifetime” (Friedman, 2005, p. 449). Consequently, the social entrepreneur is a top-class professional who turns their power towards the development of social ventures, by establishing either new organizations or developing programs within existing organizations, which is also referred to as “social intrapreneurship”,

Social Entrepreneurship Schools of Taught

There are two important schools of taught in which social entrepreneurship can be categorized. The School of Social Enterprise, which focuses on strategies or projects of non-profit organizations that serve society, so that it is seen as a method for creating and administrating organizations. And the Social Innovation School, which understands social entrepreneurship as an innovative strategy to solve societies’ problems. Some of its similarities and differences are mentioned below.

School of Social Enterprise

The school of Social Enterprise centers its perspective on the business strategy to earn income for the organization with the purposes of a social mission. Hence, instead of asking for donations, lobbying the government or building a community group, the organization must produce revenue, or be self-sufficient, as part of its business model to sustain itself and be able to tackle social problems. Replicability and scalability are considered desirable and methodological issues must be taken into account (Bravo, 2016). It considers that the social entrepreneur has a vital role in organizing and operating such social enterprises, which can operate as proprietorship, partnership and incorporated organizations, together with community enterprises, worker and consumer co-operatives, and even examples of corporate social responsibility within all types of business (Emerson & Twerskey, 1996). Defourny & Nyssens (2011, p. 20) integrate *social businesses* in this approach, as they are considered as *non-dividend companies* that do not distribute all its profits (Yunus, 2007). Social enterprises might be funded with philanthropic causes in the start-up phase, but it is generally geared towards creating self-sustained business models, therefore it is not considered a charitable organization in the long-term. But, due to the changing market trends worldwide, particularly the increase in businesses that are making a commitment to social impact, social enterprises can be difficult to identify in the general business population.

School of Social Innovation

The School of Social Innovation centers its viewpoint in innovative ideas. It considers the social entrepreneur as a person that transforms the patterns to create social value or tackles social problems in an innovative manner. Hence, in this school, innovation is the key and even though revenue, replicability and scalability are desirable, they are not compulsory (Bravo, 2016). The most important factor as stated by Dees & Anderson (2006) is on creating new and better ways to overcome social problems; therefore, business venture is not a necessary element. It is well known that social problems such as poverty, inequality and exclusion need to be tackled in an innovative way. Furthermore, within this school of thought, methodological barriers are disregarded as it aims to integrate all sectors (government, community and private businesses) as open innovations to solve social problems.

Therefore, both schools are considered relevant as they focus on different viewpoints. The School of Social Enterprise could be seen as a top-down model due to the implementation of business strategies and methodologies, whereas the School of Social Innovation could be seen as a model that begins at the bottom, with a social entrepreneur that has an innovative idea to tackle social problems and who implements his/her idea with the support of a variety of actors (i.e government, NGO's, private organizations, communities).

Social Innovation and Sustainability

Social Entrepreneurship interacts directly with innovation models to achieve sustainability; this interaction has attracted growing attention, especially from entrepreneurs and communities but unfortunately not from governments. Sustainability was defined by Oxford University (1987, p. 8) as “development that meets the needs of the present without compromising the ability of future generations to meet their own needs.” Since then, there has been much discussion about the relationship between three key dimensions: social, economic, and environmental. In 1997 the United Nations adopted the following definition, “Development is a multidimensional undertaking to achieve a higher quality of life for all people”

(United Nations, 1997, p. 1). In recent studies Carvalho (2018) has included the impact of regional and national development which is perceived indirectly by the positive impact of organizations on economic, ecological, social and psychological sustainability. Psychological sustainability is a new broad concept developed in connection with the concepts of psychological value (Carvalho & Jonker, 2015).

Therefore, sustainability has been defined by different contextual references that include the environment, the socio-economic fields, green efforts and sustainable consumption, amongst others. Some explanations also place sustainability within a change continuum whereby the boundaries between creating social value and investing in social problems are blurred. “Economic development, social development and environmental protection are interdependent and mutually reinforcing components of sustainable development” (United Nations, 1997, p. 1).

Consequently, the relationship between the social entrepreneur and sustainability is a clear one, so long as the social entrepreneur seeks to solve problems in a sustainable manner through innovation and by creating social value in vulnerable and excluded communities in a sustainable manner. Based on the aforementioned a serious obstacle is economic leverage and the achievement of income and financial projections in order to fund the social goals. Successful social innovation comes when social entrepreneurs understand how to structure alliances and implement innovative social projects to seek social objectives, using market instruments, putting into place effective management strategies and methodologies for constant improvement. Hence, the aim is to run profitable businesses. Currently, there is a tendency to bring forward social enterprises that focus on generating social and environmental value to achieve the Objectives of the Sustainable Development Goals in the fields of poverty, climate change, inequality, among others. This type of innovation has a crucial role within social entrepreneurship.

According to Mulgan, Tucker, Ali & Sanders (2007, p. 8) from Oxford's Said Business School, “social innovation refers to new ideas that work in meeting social goals.” However, it is often difficult to lobby for government intervention and to attract private capital, despite the obvious support towards social equilibrium and its direct positive economic impact within each country.

Consequently, to understand the links between social entrepreneurship, sustainability, and innovation it is necessary to recognize the importance of developing innovative sustainable ideas that consider the welfare of the communities, together with the environmental factors. In summary social enterprises can achieve innovation by bearing in mind the following six recommendations: 1) Value proposition 2) Creation of shared value 3) Innovation for building structures that optimize costs in order to achieve benefits 4) Focus resources on investment to solve social problems 5) Engage other actors 6) Invest in technology.

Social Entrepreneurial Ecosystem

The formation of a social entrepreneurial ecosystem is recognized as a fundamental activity that can affect start-up, growth and the long-term sustainability of any social enterprise as contribute to social welfare, community revitalization and economic development. Figure 1 shows a heuristic analysis for the development of social entrepreneurship which comprises an outer frame, namely the political, social, environmental and economic context, which includes features such as investment, legal framework, networks, public awareness and government support, allocation of resources, academic research, technological development, innovation, amongst other features. At the micro level the social entrepreneur is represented with all the accompanying psychological characteristics, personality traits, skills, motivation and points of view. At a meso level the organization is represented by aspects such as structure, strategy, objectives, business model and finance strategy. The convergence of these two levels materializes at a macro level where the social entrepreneurship initiatives develop and grow, together with the interactions

between the individual (social entrepreneur), the organization and the political, economic, environmental and social context. This heuristic analysis illustrates the way in which the micro and the meso level contribute to success on a macro level.

Figure 1. Heuristic analysis for the development of social entrepreneurship

Source: Cano et al., (2015) and literature review performed by the authors

Trends of Social Entrepreneurship

Currently, social entrepreneurship trends focus on the goals that have been highlighted by the 2030 United Nations agenda, namely the Sustainable Development Goals, particularly with regards to the social, environmental and economic dimensions and the importance of integrating business models that have an impact on the achievement of such goals. Hence, the trends can be related to the following five dimensions (United Nations, 2015):

1. **People:** this is related to both rights and welfare and includes poverty eradication, food security and nutrition, health and population dynamics, education and promotion of equality focused on gender equality and women's empowerment.

2. Prosperity: this includes employment opportunities and decent work for all, strong infrastructure, industrialization, sustainable consumption and production, sustainable cities and settlements and economic growth
3. Planet and environmental dimension, that includes climate change, marine resources, oceans and seas, energy, ecosystems and biodiversity.
4. Peace and political dimension that is related to peace building, reconciliation and reconstruction of the social fabric
5. Partnerships, which are related to building networks and connections to meet the sustainable development goals.

ISSUES AND CHALLENGES

Even though, social entrepreneurship has grown worldwide, some issues and challenges have arisen. Some of them are briefly described below:

Research data: the accuracy and validity of the data that shows the roots or causes of the social problem, together with the adequacy of the initiatives that are being developed in terms of human rights satisfaction and the fulfillment of needs of the beneficiary communities, the government and the social enterprises.

Financial strategies: financial leverage is key for any entrepreneurial initiative. Given the increase in social ones, international cooperation can be a good source. A crowd funding strategy could also be considered. Gierczak et al. (2015), mentions that crowd funding has gained a lot of attention recently due to the all the internet-based platforms that offer opportunities to raise money donated by all kinds of interested parties. The long-term viability and endurance depends on the relationships built with diverse stakeholders or crowd funders and the adequate distribution of resources. Self-sustainability throughout time is also an important issue to consider, hence social entrepreneurship need to seek innovative financial support in order to carryout their activities and social mission.

- Regulations– Tax and legal regulations regarding social entrepreneurships are not well defined. Rewards should be put in place for businesses that are driven by a social mission, as well as businesses that work with social enterprises under the principle of joint- responsibility.
- Public investment – Governments need to commit to improving social standards worldwide by investing in infrastructure, innovation and productivity; this has been clearly highlighted in the Sustainable Development Goals. It also includes generating a socio-political, economic and environmental ecosystem that values high-impact social entrepreneurship initiatives from local to global levels.
- Public awareness – All levels of education (from primary to higher and vocational education) should include basic concepts related to social entrepreneurship, as well as the development of specific social entrepreneurships skills in students. This includes leadership, effective communication, conflict resolution and teamwork. This will not only increase the value of socially oriented initiatives in society, but also encourage individuals to become socially conscious and develop their own innovative ideas as to create lasting social change.

Measuring impact – Social entrepreneurs have contributed to tackling social problems worldwide. However, in most cases, indicators are not established and impact is difficult to measure, making it difficult to get financial support from donors, private organizations, and banks, amongst others.

SOLUTIONS AND RECOMMENDATIONS

Social entrepreneurship is an activity that has been researched by different actors, including academics, the entrepreneurial ecosystem, NGO's and government agencies worldwide. However, a lot still remains to be done in order to measure its impact on society's well being, not just from the receiver point of view, but also from the entrepreneurs themselves from a psychological, sociological and philosophical point of view. Likewise, according to the Skoll Foundation it necessary to create social-financial models that can permanently shift the social and economic equilibrium of the beneficiaries and through this be able to reach all the economic agents involved including customers, banks, government agencies etc. who could develop portfolios that address financial difficulties (Martin & Osberg, 2015). This includes not only government grants and subsidies, but sources of finance through philanthropy, cooperatives, investors, civilian initiatives, crowd funding and corporate social responsibility schemes from profit enterprises and private entities.

At the same time, governments could provide subsidies to companies if they engage in supporting social entrepreneurship initiatives through their corporate social responsibility programs, as they are oriented towards society in general and in particular to the creation of social value. As stated by Porter & Kramer (2011) by associating with social entrepreneurs, companies not only fulfill expectation of corporate social responsibility, but they can also improve their reputation, creating strategic corporate social responsibility.

It is also considered important to empower local actors so that all their ideas can contribute to solving social problems. It is well known that often individuals might have innovative ideas, but these are never followed up due to economic, political or motivational constraints. Hence, it is advisable to seek support from the entire social entrepreneurial ecosystem (public, private, and nonprofit sectors) in order to develop those ideas. Simultaneously, the ecosystem needs to be more entrepreneur-friendly, provide support and advice to all actors and include the use of technologies to boost social entrepreneurship initiatives.

FUTURE RESEARCH DIRECTIONS

Social entrepreneurship is sometimes presented as an individually focused activity, which is performed by one person. However, social entrepreneurship is highly affected by the social, cultural, environmental and political context, together with the ecosystem around it, which supports it; with this in mind, further research is needed as to understand the influence of these factors on the development of social entrepreneurship in each country, at a local, regional and national level. Likewise, research is needed in order to find out why social entrepreneurship is still highly gendered and the ways in which more women, particularly those from developing countries, could receive support in order for them to contribute with innovative solutions. This is considered relevant given the UN development objectives, which address gender equality and sustainability.

Furthermore, it is clear that both entrepreneurship schools of thought are different in the sense that the School of Social Enterprise, focuses on the management of the organization and its social component, whilst the Social Innovation School focuses on the ideas to solve societies' problems in an innovative manner. However, these schools need to be further researched in the light of the socio-political events that are taking place in each country and/or continent. For example, at the moment, Latin American social entrepreneurship is rising, but the theoretical frameworks are still European and American based. Finally, research about the ways in which social entrepreneurship could be taught is needed, both at an

academic level and a practical level. This could foster innovative problem-solving skills in the population and could contribute to development and sustainability worldwide.

CONCLUSION

Social entrepreneurs seek innovative ways of creating social value and finding solutions to pressing problems such as poverty, environmental destruction, unequal access to education and unsustainable living, among others. Their reach also goes as far as to encompass peace and justice. Here lies the fundamental difference between them and the traditional entrepreneur who seeks profit and economic value. Likewise, social entrepreneurship is aimed at solving social problems through organized business models and strategies as highlighted by the Social Enterprise School, or innovative ideas that lead to social transformation, based on the viewpoint of the Social Innovation School.

From a disciplinary perspective social entrepreneurship exists at the intersection of the economic, social, political and environmental context, which are undoubtedly in turmoil and in need of improvement. Social entrepreneurs are aware of these issues and find opportunities by including innovation and sustainability in their social projects. From a multidisciplinary perspective, all types of professionals should develop social entrepreneurship initiatives in order to achieve the sustainable development goals. Finally, for these initiatives to succeed, the relationships and alliances between the different actors need to be developed and strengthened worldwide. This includes government institutions, private sector, academic and research institutes, financial institutions and investors, NGO's, the market and the media. If all these actors work together, the quality of life of the entire population can significantly improve.

KEY TERMS AND DEFINITIONS

Corporate Social Responsibility: Programs that are done by businesses in order to benefit society while boosting their own brands or services.

Entrepreneur: The person responsible for the management of an enterprise, usually with some element of risk and creative initiative.

Innovation: A new form of achieving or creating something.

Shared Value: A management strategy in which competitive advantage and social responsibility combine.

Social Innovation: The process of developing and implementing innovative solutions to social and environmental issues.

Sustainability: The concept of continual viability, including the avoidance of the depletion of natural resources in order to maintain an ecological balance.

Sustainable: Something that continues to be viable.

Entrepreneurial Personality: To Be or Not to Be an Entrepreneur

INTRODUCTION

Entrepreneurship has always been present in the course of human history, due to its inherent nature to create. In recent decades, this concept has become highly important, given the need to overcome constant and growing economic problems in different societies. Today, we can say that entrepreneurship is so essential and ingrained that it has itself become a culture: a way of thinking and acting oriented towards the creation of wealth through exploiting opportunities, the development of a global vision, balanced leadership, and taking calculated risks, whose result is the creation of value that benefits entrepreneurs, its enterprise, the economy and overall society.

Even so, many academics still ask, implicitly or explicitly, why we should study entrepreneurship. There are multiple ways to answer this question, and we synthesize them from three different perspectives: economic, social and academic. The Global Entrepreneurship Monitor (GEM) describes entrepreneurship as an increasing “world-wide phenomenon”. In the 90’s, an important business creation activity was developed, mainly in transitional economies, where the activity of the private sector was relatively new. Around the world, 9 out of 100 people of working age are involved in business activities, with approximately 300 million in the phase of creating a business venture. Due to this, the generation from the 21st century’s has also been labeled as *Generation E*, the most entrepreneurial since the Industrial Revolution (Kuratko, 2003).

Entrepreneurship is also an important source of employment for women, and there has been significant worldwide growth in women’s self-employment (Langan-Fox, 2005). A dominant trend in the 21st century is likely to be ethnic entrepreneurship, due to the free market, less restraining in the flow of people, and infrastructure development (Morris, Schindehutte, & Lesser, 2002).

Entrepreneurship can also greatly contribute in reducing poverty. Increasing the number and quality of entrepreneurs and business is probably one of the most useful ways to reduce poverty, since it creates employment, as well increases innovation and economic empowerment of people in low development countries with high unemployment rates. (Pick & Sirkin, 2010). These countries political systems are increasingly recognizing this, and have introduced several top-down programs to facilitate the creation of new businesses. These essentially refer to changes in laws and regulations in order to make easier the design and operation of business. Bottom-up programs have also been launched in an attempt to support

DOI: 10.4018/978-1-7998-3473-1.ch098

entrepreneurs with either financial resources (micro-credits) or increase knowledge about business. Specifically, approaches that involve the supply of financial resources have received wide attention. Within the microcredit community, influential people, such as Nobel Prize winner Muhammad Yunus (Yunus, 1999), have argued that the provision of microcredit is enough to lift people out of poverty, but does not go beyond the training required to improve entrepreneurial skills. Although both, government programs and microloans for the low or no-income individuals are necessary, these institutional and economic strategies have often failed because they do not pay enough attention to the psychological dimensions of entrepreneurship (Chliova, Brinckmann, & Rosenbusch, 2015).

In summary, entrepreneurial activity represents one of the most important engines of economic growth, being the power behind the creation of any new company, growth of existing ones, and to a large extent, creation of employment. *Entrepreneurship has come to be perceived as an engine of economic and social development throughout the World*, or as Lazear (2002) states, “*the entrepreneur is the single most important player in a modern economy*” (p.1).

Additional to this economic and social interest, we must add those reflected by the academic field. Since the first course in entrepreneurship offered in 1947 by Myles Mace at the Harvard Business School, numerous historical events have solidified it as a growing interest. For example: the *First Conference on Small Business* at St. Gallen University in Switzerland, in 1948, and the *First Academic Conference on Entrepreneurship* that took place at Purdue in 1970. In 1974, at the Annual Meeting of the Academy, the *Interest Group on Entrepreneurship* was formed, and in 1987, the Entrepreneurship Division of the Academy of Management was formed. The first conference on “The State of the Art”, took place at Baylor University in 1980, which led to the publication of the *Encyclopedia of Entrepreneurship*, in 1982, the first of six volumes published to date. These events were followed by the publication of specific journals in the field: *Journal of Small Business Management* in 1963, *The American Journal of Small Business* in 1975, which would later be called *Entrepreneurship: Theory and Practice*, *Journal of Business Venturing* in 1985, *Entrepreneurship and Regional Development* in 1989, and so on. This explosion of events has not been matched, at least as we would like, by the dedication from the professorship into teaching and researching this field. The number of professors capable of devoting all their energy to teaching and research in this area continues to be limited, even though the prospects are good, given the increase in the course offerings on entrepreneurship at universities; from the 10 courses that were estimated in 1967, to the 1064 courses that are estimated nowadays.

To this day, we can affirm that this field of study no longer qualifies as emergent; it is no longer a promise, but a reality, a reality which is greatly established (Fayolle & Riot, 2016). Entrepreneurship is, therefore, a rapidly growing field of knowledge that is achieving better and greater social and scientific recognition.

BACKGROUND

Personality as a Determining Factor for Opportunity Development

There is a broad consensus, both in literature and practice, about the sequence on the process of creating business. This process begins by (1) recognizing an opportunity, which leads to (2) carry out a rigorous analysis of it, and ultimately results in (3) a business plan that gets implemented.

Opportunity recognition is understood as a process or processes through which individuals identify an opportunity. In this way, *recognition* constitutes a conceptually different stage from *exploiting* an op-

portunity. More specifically, opportunity recognition includes three different processes (Ardichvili *et al.*, 2003): perception, discovery, and creation of a business concept. These sub-processes are accompanied by a continuous assessment, that allows the entrepreneur to question and value the opportunities in the different stages of the process.

In its beginnings, research on entrepreneurship was developed mainly on the basis of Economic Theories, dominated by the approaches given by Schumpeter (1934) and Kirzner (1973). However, the economic approach has limitations when it comes to explaining the human and social process that accompanies entrepreneurial activity. In this regard, Zahra *et al.* (2005) points out that the psychological approach can eliminate some of established ideas about the ways in which entrepreneurs make decisions, by sustaining its analysis in both, the rational and non-rational elements that determine decision-making processes. This cognitive approach has its roots in psychology and sociology, which provide important new contributions to the understanding of entrepreneurial behavior.

The *psychological approach* has shown that internal attributes of an individual are stable, and that they differ between people. With this approach, and based on the work of recent authors, such as Ardichvili *et al.*, (2003) or Zahra *et al.* (2005), we can argue that the *recognition and exploitation of business opportunities depends on the existence of individuals who possess certain personality traits* that, combined with their own personal or social circumstances, lead to the formation new enterprises.

This approach takes into account the importance of the personality of an entrepreneur in this process, which allows us to map a set of characteristics that differentiate them from those who are not entrepreneurs. The main attributes discussed in this approach -with the exception of the demographic characteristics of individuals, such as sex, age or nationality- are (and among the most frequently accepted): creativity, optimism, self-efficacy, propensity to take risks, need for achievement, and locus of control. Although some of these, as an “entrepreneur” trait, have been questioned, much of the literature has actually converged in their conclusions on these variables and the entrepreneur profile (Thomas & Mueller, 2000).

While it is true that the relationships between personality traits and entrepreneurial behavior are frequently studied and analyzed in research, there is nonetheless certain skepticism as well about the intensity of this relationship among scholars. Although some reviews in this regard conclude on the existence of a positive relationship (Rauch & Frese, 2000), other reviews conclude that there is no such relationship (Brockhaus & Horwitz, 1986; Gartner, 1989; Low & MacMillan, 1988).

In this regard, we would like to point out that the meta-analyses done actually provide evidence of the predictive validity of personality traits in entrepreneurial behavior (Brandstätter, 2010, Collins, *et al.*, 2004, Gorgievski & Stephan, 2016, Rauch & Frese, 2007; Stewart & Roth, 2001, 2004, Zhao & Seibert, 2006; Zhao, Seibert, & Lumpkin, 2010) and suggest the analysis of contingencies that may impact on the size of this relationship.

That said, the next step is to ask: which are these personality traits? The number of traits associated to entrepreneurs that can be found just by looking at the literature is actually *huge*. For example, Hornaday (1982) listed 42 traits related to entrepreneurs. Rauch and Freese (2007) found 51 different traits in the 104 articles included in their meta-analysis. As we can see, there are so many that, at some point, it becomes reasonable to doubt if there actually exists such a being. Scientifically-wise, it does not make sense to consider those with weak empirical support, however. Out of the 51 traits identified by Rauch and Freese (2007), only 11 were actually found to be related, or highly related, to entrepreneurship.

Fortunately, literature has begun to converge a certain group of traits which, to a greater or lesser extent, many researchers seem to agree with. Considering the works of different authors (e.g. Filion, 2003, Vecchio, 2003) and the traits common to these works, we can state that the main traits of the entrepreneurial personality are: Locus of Control, Self-efficacy, Risk Taking and Proactivity. Other works have also confirmed this relation (Sánchez, 2005, Sanchez, 2010).

Locus of Control

Relates to the belief that one's actions determine the outcomes obtained by it –internal locus of control-. People with a high internal locus of control think that they are able to control results, meaning they will devote more effort and persistence towards these, which, in turn, would help in venture creation and its success. Conversely, people with external locus of control can be more passive. If one thinks of oneself incapable of controlling outcomes, there is no reason to actively change the environment and start a business. Korunka, Frank, Lueger and Mugler (2003) found, in a sample of nascent entrepreneurs, that locus of control was related to other traits, such as need for achievement and personal initiatives. Filion (2003) states that internal locus of control is a trait frequently attributed to entrepreneurs, although not exclusive, given that it is also found in successful people, whether they are entrepreneurs or not. Lastly, it should be noted that this trait can be learned, as some authors have pointed out (Hansermark, 2003).

Self-Efficacy

Self-efficacy refers to one's own conviction of capability to effectively organize and execute actions for any required result (Bandura, 1997, Chen, Greene, & Crick, 1998). In other words, self-efficacy is an attribution of personal competence and control in a given situation, and reflects the perception of one's personal capacity to perform a specific job or task. This attitude affects choice of action, as well the amount of effort given to it. It also is the main predictor for occupational choice. The relationship between self-efficacy and entrepreneurship is reasoned because: first, people avoid careers and environments that they believe exceed their abilities, hence, choose those for which they judge themselves capable (Krueger & Dickson, 1994). Second, because entrepreneurship entails significant risks and difficulties, such that entrepreneurs need, by default, high levels of self-efficacy. Third, given that self-efficacy predicts career interest and choice; perseverance when facing difficulties, as well personal effectiveness (Waung, 1995), it must also be related to entrepreneurship. Lastly, since incentive to act is greater when entrepreneurs believe that their actions will have achievable results, self-efficacy becomes a crucial determinant for their successful entrepreneurial endeavors (Sánchez *et al.*, 2005). Based on this type of reasoning, several authors have shown that self-efficacy is a distinctive attribute of entrepreneurs when compared to other business positions, or the general population (Markman & Baron, 2003). Likewise, other empirical studies have linked self-efficacy to entrepreneurial, personal and financial success, measured generally by annual earnings.

Risk Propensity

This is defined as a personality trait that determines a tendency and disposition of individuals to take risks. Individuals with high scores in this dimension will have a propensity for high-risk behaviors; that is, they're willing to consider alternatives whose end result may drift from their framework of expectations. On the other hand, subjects with low risk propensity will tend to be low risk takers, and will avoid alternatives that may lead to results that vary greatly from the ones expected. The concept of risk propensity has been related to entrepreneurship; it is obvious that entrepreneurial activity implies, by definition, taking risks of some kind. Following Covin and Slevin (1989), risk taking propensity is, along with proactivity and innovation, one of the three dimensions of the so-called entrepreneurial orientation. In this framework, risk propensity refers to the willingness of a person to commit acting on opportunities even when they are likely to fail.

Proactiveness

9

This refers to the tendency to initiate and maintain actions that directly alter the surrounding environment. Proactive people identify opportunities and act on them; they show initiative, carry out direct actions and persevere on it until they achieve a significant change. In contrast, people who aren't proactive fail to identify and act on these opportunities. Proactivity implies an emphasis on anticipating and preventing problems before they occur, and an orientation for action that includes interpreting norms in a creative fashion, and having high level of persistence and patience in order to achieve the desired change. Proactivity is another of the indispensable dimensions that Covin and Slevin (1989) include in the so-called entrepreneurial orientation, referring to it a necessary factor to achieve entrepreneurial behavior, which implies perseverance, adaptability and willingness to take responsibility for failure. Proactive enterprises are those that are more likely to seek opportunities in the external environment. As for established firms, the majority of research has referred to two attributes that stem from pro-activeness: an aggressive behavior towards other firms, and the search for favorable business opportunities, finding that both are greater in the case of entrepreneurial firms. In other studies, the relationship between having a proactive attitude and entrepreneurial behavior has been found, both, in established entrepreneurs and the general population (Becherer & Mauer, 1999). Lastly, there is also evidence of a relationship between proactivity (in the context of entrepreneurial orientation) and business development (Junehed & Davidsson, 1998), as well career success (Seibert, Kraimer, & Crant, 2001). Shapero (1982) has suggested that this personal propensity to act on opportunities is one of the factors that affects the intention-behavior relationship, by either hindering or facilitating the development of these intentions. Specifically for entrepreneurship, Crant (1996) found that entrepreneurial intentions were positively related with having a proactive attitude. Likewise, this type of personality orientation has been referred in the literature (Shapero, 1982) as an important precursor of intentions and entrepreneurial potential.

Different works have also highlighted the importance of these variables in entrepreneurship (Sánchez *et al.*, 2005, Sánchez *et al.*, 2014. Sánchez & Hernández-Sánchez, 2014, among others), as well as its importance as a predictor of entrepreneurial intention (Sánchez *et al.*, 2005).

Differences in these traits has also been examined considering gender in developing entrepreneurial intentions (Sánchez *et al.*, 2007; Sánchez *et al.*, 2008; Sánchez and Licciardello, 2012; Sánchez & Hernández -Sánchez, 2014). For example, in Sánchez *et al.* (2007), differences were found between men and women within their considered variables, as well as their intentions for business, however, these weren't fully reproduced in Sánchez & Hernández-Sánchez (2014) where gender differences were found in self-efficacy. This finding is consistent with previous studies (Costa, Terracciano & McCrae, 2001) that support the idea that women show, in general, predominantly communal / expressive traits, while men score higher in egocentric / instrumental traits. On the other hand, they also suggest that gender stereotypes are widely established in culture, in the sense that the process of socialization promotes the development of certain egocentric features, such as business self-efficacy, to a greater extent in men than in women.

In summary, these results are in line with the predictions proposed by the double-impact model of gender (Abele, 2000), in reference to the effect of gender roles and stereotypes in the development of certain psychological characteristics that play a role in career choice. In our case, we have found that gender moderates the effect of self-efficacy in entrepreneurial intentions, where men feel more capable to start a business, and are more likely to do so than women.

These results can also be explained from a person-organization adjustment perspective, that is, we can explain the development of business intentions as a result of an agreement between the personal

characteristics of an individual and the requirements for its creation. People who show certain entrepreneurial traits, such as self-efficacy, will be more likely to choose a business career. Given that these results suggest that men are higher in this trait than women, we can explain some of the low participation of women in business initiatives due to a maladjustment between their personal traits to the qualities required to create a business.

Contrary to expectations, results have not been able to show the existence of gender differences in other business features, specifically, locus of control, risk propensity, and proactivity. For example, Cromie (1987) found no significant differences between men and women in dimensions strongly related to the entrepreneurial process, such as the need for achievement, locus of control, primacy of companies, trust, independence and planning. Therefore, this study joins previous literature that offers only partial support for gender differences in certain psychological dimensions.

Broad Personality Traits

There is a body of work (Brandstätter, 2011; Obschonka *et al.*, 2013; Zhao *et al.*, 2010) that defends the study of entrepreneurial characteristics using the Big Five personality traits model (extraversion, conscientiousness, openness, agreeableness, and neuroticism). These have a genetic basis, and are relatively stable throughout life, suggesting that biological factors are also important in entrepreneurship. This is supported by genetic studies that show that entrepreneurship has an important biological relationship (Nicolaou *et al.*, 2008), which can be explained, at least in part, by the mediating mechanisms of these Big Five traits (Shane *et al.*, 2010). Hence, to understand the personality of the entrepreneur, it is necessary to take into account the biological foundations of personality, as is the case of the Big Five.

Studies have analyzed each of these five traits both, jointly and isolation, and their effects on entrepreneurship. Both approaches can help to understand personality and its effect on entrepreneurship, although if one really wants to understand the individual as a coherent whole, it is more fruitful to consider these traits within the individual using a holistic approach. Research has found entrepreneurs scores high on extraversion, conscientiousness, and openness; while low scores on agreeableness and neuroticism (Zhao and Seibert 2006, Zhao *et al.*, 2010). This broader profile predicts entrepreneurial behavior in a more consistent and robust way than the simple model of the Big (Obschonka *et al.*, 2013, 2014). Other research has pointed out the importance of these traits to predict business behavior and intentions, attitudes, beliefs of control, skills and social capital (Arnaud 2011, Obschonka *et al.* 2016a, b, Stuetzer *et al.* 2013, for an overview of the studies see also Obschonka *et al.*, 2013). Other research shows how these Big Five can help explain a) gender differences in entrepreneurship (Obschonka *et al.*, 2014), b) regional differences (Audretsch *et al.* 2016, Obschonka *et al.* 2013), c) differences in regional economic growth (Stuetzer *et al.*, 2016b), etc.

Rauch & Frese (2005) conducted a meta-analysis and found that broad, general personality traits (such as Big Five) were significantly related to entrepreneurial success ($r = .151$), although this relationship is smaller when considering specific traits, where $r = .231$. These differences between specific features and general features are more pronounced when we consider business creation, where general personality measures are not significantly related, while the specific measures are ($r = .244$).

This differentiation between general or distal traits and specific or proximal traits gives rise to two important issues. First, research that focuses on specific traits can provide lines of intervention to improve the entrepreneur mind. For example, some educational programs aim to promote these specific traits, such as self-efficacy and risk-taking propensity, in order to promote entrepreneurial behavior (Sánchez, 2011). Second, to what extent these more specific, concrete personality characteristics can be defined

as personality “traits”, when traits are conceptualized as relatively stable personality characteristics, as in the case of the Big Five. Perhaps it would be more correct to define these specific traits as attitudes and belief patterns using the term “traits” exclusively for the level of the Big Five.

Obschonka & Stuetzer (2017) applied the *FFT Personality System* model by McCrae & Costa (2008) specifically for the purpose of measuring an entrepreneurial personality, where personality is considered as a system. The result of this application was called the EPS model (Entrepreneurial Personality System). From this model, these authors try to integrate the general personality traits, or basic tendencies, with the “specific features” of personality (Figure 1). These authors found a positive relationship between the entrepreneurial Big Five profile and each of the characteristic entrepreneurial adaptations studied.

Figure 1. Relationships between specific and basic traits. Adapted from the *Entrepreneurial Personality System Model Personality System (EPS)* (Obschonka & Stuetzer, 2017)

The Cognitive Approach, Complement To Personality Traits

Personality research has been complemented with cognitive approaches as well (Mathews, 2018; Sánchez *et al.*, 2011, Sánchez, 2012, 2014). Regarding the study entrepreneurship, this approach arises as a response to the limitations of the traits' orientation. Its objective is to explain entrepreneurial behavior through cognition. Understanding the entrepreneurial thinking represents a fertile field of research that has not been well exploited.

The cognitive approach is characterized by the study of certain types of cognitions that could explain aspects such as: what defines and differentiates an entrepreneur, their behavior and success in business, among others. Researchers who use this approach believe that cognitive aspects are the elements that differentiate entrepreneurs from non-entrepreneurs, which range from beliefs to their values, cognitive styles and mental processes.

In the last decade, Cognitive Psychology has made important contributions to the field of entrepreneurship. It has studied aspects such as the cognitive styles of the entrepreneur (Boucknooghe *et al.*, 2005), entrepreneurial self-efficacy (Markman, Baron & Balkin, 2005, Oliveira, Garrido, & Sánchez, 2005), heuristics in decision-making (Mittchel, *et al.*, 2007, Tversky & Khaneman, 1973), even structures of knowledge that the entrepreneurs have about enterprising itself, the so-called scripts (Mitchell *et al.*, 2000, Smith *et al.*, 2009), etc. Knowing the mechanisms behind these cognitive elements has facilitated the task of understanding how entrepreneurs perceive and interpret information, and how they use it to start and have a successful business.

Multiple studies have highlighted the role of scripts, self-efficacy, thinking styles and heuristics in the action of start-ups. In Sánchez *et al.*, (2011) the most relevant contributions of cognitive psychology to the field of entrepreneurship are reviewed and pointed out, as well as some of the limitations and new lines of research.

In a later work, Sánchez (2014) analyzed the differences of cognitive skills in entrepreneurs from multiple levels of success with respect to their own perceived success and company growth. Their results confirm that entrepreneurs with high scores in cognitive scripts have higher levels of perceived success than entrepreneurs with low scores in cognitive scripts.

One of the most developed and successful cognitive constructs is metacognition. In the words of Schraw and Dennison (1994), *metacognition* refers to the ability to understand, control and reflect on one's own learning. It is a cognitive process of a higher order that allows to organize what individuals know about themselves, that is, about their own learning and knowledge, but also about other people (perceptions about how people think), tasks (the nature of the information acquired when performing a task), situations and the changing environment (how the information is used in various contexts); and strategy (procedures to ensure that it is adequate to achieve the desired goal), in a way that facilitates dynamic and effective cognitive functioning.

In this way, this ability to understand, control and reflect on one's learning has a relevant weight in decision-making, as it allows the subject to identify possible alternatives to carry out a task or solve a problem, thus, to make a decision according to their own motivations and the context in which they are immersed (Glasspool & Fox, 2005, Higham & Gerrard, 2005).

Several authors point out that metacognitive capacity begins to develop at a very early age, rapidly increasing during childhood and adolescence, that is, as people get older, the accuracy of the metacognitive processes also increases, becoming a key element in the processing of information in adulthood (Koriat & Shitzer Reichert, 2002). This ability varies by individuals, and there is no empirical evidence to suggest that metacognition can be developed through training (Schmidt & Ford, 2003).

Haynie (2005) expanded the concept of metacognition, adding processes of higher order, such as metacognitive awareness. The awareness that the person has about having this skill works as an important strategy for successfully dealing with different situations, since consciousness allows people to plan, sequence and follow their learning in a way that directly improves performance.

A product of metacognition is the capacity for cognitive adaptation, understood as the ability to evolve or adapt decision-making processes in an adequate and effective way, based on feedback from the context (inputs) in which cognitive processing is involved (Haynie & Sheperd, 2009). This ability

is possible through the development of strategies that serve to promote the process of thinking about thoughts, or more precisely, metacognition.

As for entrepreneurship, cognitive adaptation is a key competence. For this reason, researchers in this field are making an effort to develop instruments that measure this ability in a way that allows us to predict success in making decisions at new learning situations for business creation (Haynie, Shepherd & Patzelt, 2010).

Haynie et al (2010) conceptualize and measure cognitive adaptability as the aggregate of five theoretical metacognitive dimensions: goal orientation, metacognitive experience, metacognitive control and supervision. The main assumption is that metacognitive awareness represents a bridge to cognitive adaptability and is based on the following logic: people perceive, and subsequently assign meaning to the characteristics of the environment in the context of their own objectives. Afterwards, they add that information to their metacognitive knowledge and metacognitive experiences to generate multiple decision-making structures focused on interpreting, planning, and implementing objectives to manage a changing environment. From this set of structures, the subject selects one and carries it out (metacognitive control) eliciting some result (cognitive and / or behavioral). These results are related to the objectives of the individual, who will use review mechanisms to generate and select new decision-making contexts depending on the new circumstances.

These authors defend that metacognition represents the cognitive basis of entrepreneurial thinking, and that people who make decisions under metacognitive processes are more aware that each specific situation can be analyzed from different points of view and, therefore, that different alternatives should be considered, as well take into account feedback for future decisions. Thus, the more metacognition the person has, the more adaptive it's response in a changing environment.

As indicated by Haynie *et al.*, (2010), most of the studies on business success have focused on understanding how “success” itself comes to happen its background, especially, its relation with prior knowledge that entrepreneurs have about the business sphere, showing how business failure relates to lack of prior knowledge, or how people with no experience detect less business opportunities. Thus, while much research has been done on the influence of prior knowledge on business success, very little has been studied about the abilities and skills of people, which could dampen the negative consequences that come from this lack of knowledge. Among these capabilities, these authors highlight the capacity for cognitive adaptation.

Taking as key competence the ability to detect and adapt to uncertainty through the use of business knowledge, but that many people have little previous knowledge about business, Haynie *et al.* (2010) used MAC to study the role of metacognitive ability and feedback in the successful completion of an entrepreneurial task by people who have no previous experience in entrepreneurship. They found that metacognitive ability helps explain why some inexperienced people in the entrepreneurial process are more able to use feedback than others to appropriately adapt their decision-making processes, consistently with the decision-making process of a sample of entrepreneurial experts.

FUTURE RESEARCH DIRECTIONS

Entrepreneurship activity represents one of the most important aspects of a country's economic growth, and people who do these types of activities seem to have certain personality traits that differentiate them from other people. In general, the meta-analyzes carried out on entrepreneurship and personality make this clear, and not without certain nuances, which we will detail below.

Differentiating between specific and general personality traits can be useful to clarify the relationship between personality and entrepreneurship. Specific traits have a higher relation with the creation and success of business than more general traits.

A greater adjustment between dependent and independent variables may be useful to clarify the relationship between personality and entrepreneurship. Correlations increase if the dependent variable is highly relevant for the independent variable, and it suggests developing different hypotheses in the relationship between specific traits with specific dependent variables. For example, the need for autonomy may be more related to survival than to growth.

It is also important to consider other issues of interest such as: the level of analysis (for example, personality is usually assessed by analyzing at the individual level, while success at the company level), possible mediators or moderators in the personality-entrepreneurship relationship (general personality traits, for example the Big Five, are not directly related to success, but mediated by processes, such as motivations, cognitions, etc.), the methodological quality of research, more longitudinal studies, and other personal and non-personal (i.e. external) variables, such as cognitive ability, strategies, environment, etc. A configurational approach can be useful to explain the specific and general entrepreneurial personality structures and in this way contribute to a better understanding of the construct and improve its predictive power.

CONCLUSION

In short, the study of entrepreneurs' personality is a topic of great scientific interest, given that the influence of these traits may be stronger in this population than in other professions, as the entrepreneurial role provides, a priori, more freedom to choose and change the environment, as well to act according to personal preferences and goals.

KEY TERMS AND DEFINITIONS

Agreeableness (Friendly/Compassionate vs. Challenging/Detached): Tendency to be compassionate and cooperative rather than suspicious and antagonistic towards others. It is also a measure of one's trusting and helpful nature, and whether a person is generally well-tempered or not.

Conscientiousness (Efficient/Organized vs. Easy-Going/Careless): Tendency to be organized and dependable, show self-discipline, act dutifully, aim for achievement, and prefer planned rather than spontaneous behavior.

Extraversion (Outgoing/Energetic vs. Solitary/Reserved): Energetic, surgency, assertiveness, sociability, and the tendency to seek stimulation in the company of others, and talkativeness. High extraversion is often perceived as attention-seeking and domineering. Low extraversion causes a reserved, reflective personality, which can be perceived as aloof or self-absorbed. Extroverted people may appear more dominant in social settings, as opposed to introverted people in this setting.

Locus of Control: The degree to which people believe that they have control over the outcome of events in their lives, as opposed to external forces beyond their control.

Neuroticism: Is one of the Big Five higher-order personality traits in the study of psychology. Individuals who score high on neuroticism are more likely than average to be moody and to experience such feelings as anxiety, worry, fear, anger, frustration, envy, jealousy, guilt, depressed mood, and loneliness.

Personality: Pattern of attitudes, thoughts, feelings, and behavioral repertoire that characterizes a person, and that has a certain persistence and stability throughout his life, so that the manifestations of this pattern in different situations have some degree of predictability.

Self-Efficacy: Is an individual's belief in their innate ability to achieve goals. Albert Bandura defines it as a personal judgement of "how well one can execute courses of action required to deal with prospective situations"

Entrepreneurial Education

INTRODUCTION

The entrepreneurial spirit is an essential ingredient for guiding the economy onto paths of sustained competitive growth. To understand the relationship between entrepreneurship and economic growth, it can be useful to refer to the Schumpeterian concept of “creative destruction”. According to this concept, development is driven by the disruptive action of entrepreneurs who introduce innovations with the potential to transform the rules of the game and replace existing firms in the industry, even transforming the industry itself (Richardson, 2004).

The Green Paper on Entrepreneurship in Europe (European Commission, 2003) marked the crucial point when the European Commission began to highlight the importance of business and entrepreneurship in developing a more dynamic and competitive Europe. Based on Eurostat data from 2009, the European Commission estimated that new companies (mainly SMEs) created more than four million jobs a year in Europe (European Commission, 2013: 4). Since then, entrepreneurial creativity and new entrepreneurial initiatives have been considered as a crucial factor in boosting job creation (European Commission, 2013, 2016). Along the same lines, the White Paper titled Embracing Innovation: Entrepreneurship and American Economic Growth (NCOE, 2001) reported that 350,000 fast-growing firms accounted for the creation of two-thirds of all new jobs between 1993 and 1996. A study from the US Census Bureau (Business Dynamics statistics) (Haltiwanger, Jarmin & Miranda, 2009) estimated that without the jobs created by new companies, the average net growth of employment would have been negative in the United States during the Period 1980-2005.

The Green Paper (European Commission, 2003:8-9) noted additional benefits of entrepreneurship: wealth creation; economic growth; fostering economic and social cohesion; boosting business competitiveness, productivity and the overall competitiveness of the economy (by incentivizing greater competition, which should encourage innovation); maximizing personal potential; helping to solve social and environmental problems; and contributing to the development of social economy and social innovation.

The entrepreneurial spirit is also a quality that endows people with greater creative and innovative capacity. Gerber (1997) emphasized that entrepreneurial activity converts any situation into an exceptional opportunity, defining the entrepreneur as a visionary. Therefore, entrepreneurship is an attribute to be developed in order to promote progress towards a knowledge economy. It is also an essential component of the systemic response required of people and organizations in order to adapt to uncertain and complex future environments (Stevenson, 2004, Gibb, 2007).

However, starting up new companies or managing them in such a way as to ensure accelerated growth are in no way easy tasks. They require uncommon specific attitudes (such as positive risk confrontation or creative guidance) and skills and knowledge that are difficult to develop simply through the type of classroom study that does not involve active and participatory learning processes. In other words, the entrepreneur must possess a series of competences to be able to carry out his/her responsibilities successfully (Hisrich, Peters & Shepherd, 2005; Van Gelderen et al., 2008). Although many people believe that

DOI: 10.4018/978-1-7998-3473-1.ch099

creating a new company is simply a matter of financial resources, or that we are all capable of becoming entrepreneurs, in reality it requires a wide range of financial and non-financial competences to create a viable, successful company, and most people lack such skills.

In light of the above, a series of innovative initiatives have been launched in European universities, mainly focused on sparking entrepreneurship among students and teaching the basics of how to channel the motivation for business creation (Coduras et al., 2008). The stock of aspiring entrepreneurs swells whenever a significant number of students take a special interest in gaining a complete and rigorous knowledge of economics, finance or business management, by choosing university studies focused on economic and business degrees or deciding to become self-employed through opening their own business.

However, there is a lively debate about the poor response to the growing awareness of the importance of entrepreneurial education (Matlay, 2005, Kirby, 2006, 2007, Duval-Couetil, 2013). Among the first disturbing reports was the one published in the United Kingdom by NCGE/Barclays Bank. Its conclusion was that students who wished to become entrepreneurs did not have a positive university experience; the percentage of students aspiring to be entrepreneurs fell between the first and last year of their studies (Gibb & Hannon, 2006).

Este artículo analiza qué se entiende por educación emprendedora, precisando la definición y el alcance del concepto. This article analyses what is meant by entrepreneurial education, specifying the definition and scope of the concept. El artículo también trata las competencias, actitudes y aptitudes que el emprendedor debe reunir. It also addresses the competences, attitudes and aptitudes that the entrepreneur must acquire. Por último, el análisis se extiende sobre los antecedentes, principios, modelos, experiencias y buenas prácticas que podrían inspirar la plena instauración de la educación emprendedora. Finally, the analysis covers the background, principles, models, experiences and best practices that could help to establish a comprehensive entrepreneurial education.

BACKGROUND

In spite of the potential for economic growth and improved social and individual welfare that entrepreneurship theoretically brings with it, the average citizen tends to lack entrepreneurial spirit and literacy in economics, finance or business management, with a consequent negative effect on business vocations. The Green Paper on Entrepreneurship in Europe (European Commission, 2003) and the Small Business Act for Europe have already highlighted, on the basis of Eurobarometer statistics, that Europeans prefer to be employed by others while in the United States they prefer to create their own business. Data from the period 2002-2012 indicate that 58% of the European population (EU 27) prefer to be employed by others, with a 9-point rise over the decade, compared to 37% that would like to be self-employed (a drop of 8 points over the same period). Europeans show significantly less entrepreneurial vocation than their counterparts in the United States, where the respective percentages are 46% and 51%, although there has also been a 4-point reduction in those preferring self-employment. The contrast is even greater with countries such as Turkey and Brazil, where 82% and 63% of the population, respectively, want to launch their own business.

Although the first entrepreneurial action tends to translate into the birth of a micro-enterprise, entrepreneurial capacity is also demonstrated in forging projects with high growth capacity, in which new production units quickly grow to medium or large dimensions, or are able to rapidly enter new markets. The entrepreneur is not always bounded by the glass ceiling that slows the development of nascent companies, meaning that in an entrepreneurial economy the average size of companies will be greater.

This is indicated by studies comparing Europe and Latin America (Hall & Jones, 1999), which find that European companies over 26 years old are 7 times bigger than companies under 6 years old, while Latin American companies only triple in size over the same period. Hsieh & Klenow (2014) report similar results for the comparison between U.S. and Mexican companies: U.S. companies that are over 40 years old have 8 times as many workers as companies that are less than 5 years old, whereas Mexican companies only double in size over the same age range.

The belief in the importance of entrepreneurship and entrepreneurial propensity in many countries has been weakened by numerous circumstances that limit the development of entrepreneurship and the resulting value-creating initiatives. The Green Paper on Entrepreneurship in Europe (European Commission, 2003) recognized a wide range of obstacles that made people more reluctant to start up new businesses, including financial ones. The main barriers, however, are institutional.

The current institutional framework, both formal (laws, norms and regulations) and informal (beliefs, attitudes and customs) provides incentives and opportunities that influence the behaviour of the different agents operating in the environment. Flawed regulatory design represents one barrier that should be removed in order to encourage entrepreneurial spirit. Small-scale entrepreneurs argue that the main obstacle to the creation and survival of their business is the cost entailed in fulfilling all the administrative requirements, which is disproportionately higher than the cost faced by larger companies.

But the institutional environment also defines, creates and limits aspirations, intentions and business opportunities, thus affecting the scope and speed of growth of entrepreneurial projects (Shane, 2003). The well-known study by Covin & Slevin (1989) pointed to the dominant social and cultural values in the country as a significant predictor of entrepreneurial intentions (explaining 7.5% of its variation). The first relevant attitudinal problem that hinders the entrepreneurial spirit is the image of the entrepreneur and the perception of the value of a business career. Even when it is accepted that companies are wealth generators, they tend to dissociate themselves from the entrepreneur who was the architect of their success and, therefore, deny entrepreneurs the recognition and social prestige they deserve.

Another attitudinal problem is that the unsuccessful entrepreneur is discredited by failure. It is not generally understood that an early failure is often the prelude to the success of a new entrepreneurial project. This is not an unusual situation: bankruptcy is the reason behind 15% of corporate closures and a decade ago, and therefore before the financial crisis, it already affected an average of 700,000 European SMEs annually, with 2.8 million workers.

This analysis suggests that the educational system cannot remain oblivious to the challenge of stimulating entrepreneurship. The main factor influencing the long-term development of entrepreneurial spirit is training (Lee et al., 2005). The Green Paper on Entrepreneurship in Europe (European Commission, 2003) emphasizes the great impact that the development of competences in this field in order to move towards an entrepreneurial society. Key impacts were then clearly defined in the communication Rethinking Education: Investing in skills for better socio-economic outcomes - COM (2012) 669 (European Commission, 2012:2-4).

FOCUS OF THE ARTICLE

The Importance of Entrepreneurial Education

Entrepreneurial and business training not only facilitates young people's personal growth—helping them to become more creative, informed and self-confident—it also eases their incorporation into the labour

market through self-led projects. The importance of education aimed at boosting entrepreneurial spirit is justified by the direct relationship between knowledge of the entrepreneurial process and the probability of creating a new company. The Eurobarometer survey and the British Household Survey (2002) empirically attest to the fact that people who had more contact with entrepreneurial initiatives are more inclined to work for themselves. Similarly, the GEM survey points out that people who are confident in their skills and experience are 2 to 7 times more likely to create or manage a new company; if they know someone who has recently created a company, that probability is between 3 and 4 times higher (European Commission, 2003:15-16).

The Green Paper also stresses the enormous importance of education in stimulating a positive attitude towards entrepreneurship, encouraging people to take advantage of the career opportunities offered to them, and using the knowledge they have accumulated to act entrepreneurially within companies, universities and R&D centres (intrapreneurship). Education has a powerful role to play in ensuring that the social perception of the image of the entrepreneur and his/her contribution to social well-being reflects the reality, highlighting not only opportunistic behaviour, but also the models of responsible behaviour displayed by many entrepreneurs who work to meet social needs. At this point it is worth remembering, following Baumol (1990) and Baumol & Storm (2010), that not all entrepreneurial activity is productive. It is thus crucial to differentiate between productive entrepreneurs, who contribute positively to growth, and the unproductive or even socially destructive entrepreneurs that cause economic dysfunction.

Entrepreneurial education must make future entrepreneurs aware of the role they should play in the community and their critical role in economic and social change, acting as a catalyst for development and prompting a systemic, mutually-supportive response to change (Stevenson, 2004; Kirby, 2006).

The theoretical contribution of entrepreneurial education to employability, job creation and the creation of new companies has been confirmed in several studies that reveal a wide range of positive effects. The report published by the Thematic Working Group on Entrepreneurship Education of the European Commission (European Commission, 2014B: 10), based on GEM data from 2003 to 2012, highlighted the positive effects of entrepreneurial awareness and self-perception of skills for starting a new business. Another research paper on the impact of the Youth Entrepreneurship Strategy (YES) in the United Kingdom reported a rise in entrepreneurship among young people aged 18 to 24, from 3.5% to 10.2% between 2002 and 2011 (GEM UK, 2011).

There is also an extensive literature that highlighted the positive contribution of higher education to entrepreneurial activity, in providing a sufficient quantity and quality of graduates to successfully launch and manage new businesses (Gibb, 2006; Matlay, 2006; Jones, 2010). Universities have been designated as the educational institutions that bear the greatest responsibility for channelling new generations towards entrepreneurship in future industries (European Commission, 2008, 2010, 2012). A study carried out in Denmark concluded that the percentage of students who created their own company while they were a student increased by 50% if they had received entrepreneurial education (FFE-YE, 2012:7-8). At the European level, according to GEM 2013, early entrepreneurship among young people aged 18 to 29 rose from 4.3% to 6.7% between 2003 and 2012, showing an opposite trend to that of youth employment (European Commission, 2014b: 10).

The Development of Entrepreneurship and Entrepreneurial Skills

In order to define the scope of entrepreneurial education and the skills it incorporates, it is necessary to first define the concept of entrepreneurship, since fostering this quality is the goal of such education. This is not an easy task because there is a great deal of conceptual ambiguity associated with this term

(Sexton, 1994; Nabi & Holden, 2008; Sewell & Pool, 2010) due to its multidimensional nature and the fact that it is present in very different contexts and in all kinds of organizations.

The quasi-official definition of the term entrepreneurship adopted by the European Commission, (2003:6), cited at the end of this paper, adopts an interdisciplinary approach that combines elements of its economic, sociological and psychological conceptualizations. The Green Paper (European Commission, 2003:6-7) also specifies that the entrepreneurial spirit combines an attitude marked by willingness to take risks, an attraction to independence and personal fulfilment, creativity and innovation, and a sound management ability that goes beyond daily management and affects the company's strategy. It remarks that "to turn a business idea into success requires the ability to blend creativity or innovation with sound management and to adapt a business to optimize its development during all phases of its life cycle". It is thus understood that entrepreneurship also entails a process of creating economic activity.

The universality of the concept is reflected in the fact that the entrepreneurial spirit can be found in any industry or type of business, irrespective of its nature, size and ownership structure. It should also be clarified that entrepreneurship can occur both in the creation of a new company and in existing companies. Therefore, despite its interdisciplinary nature, the fundamental axis is the economic element of the entrepreneur's role in the market.

The concept of entrepreneurial spirit refers then to two types of competences with different degrees of specificity (European Commission/EACEA/Eurydice, 2016:22; European Commission, 2004):

- The **more specific competences** are those related to professional development as an entrepreneur or promoter of a new company, whatever its size. Developing a new company requires specific knowledge and behaviours to ensure the eventual success of new productive ideas. The focus is thus on economic, business, management and financial competences.
- The **more generic competences** are those skills useful for people in any social context, including entrepreneurship. This second group of competences is much broader and more transversal than the first, since it is applicable in any social and economic context. Therefore, it particularly emphasizes the entrepreneur's personality profile, attitudes and certain skills that can be practised in any domain, including business, society at large, culture or politics (Wickham, 2006).

Recommendation 2006/962/EC of the European Parliament and of the Council of 18 December 2006 (European Parliament & European Council, 2006:17) argues that all learners should develop a sense of initiative and entrepreneurial spirit as a key generic cross-skill.

Entrepreneurial Education Concept

The approaches, objectives and content of entrepreneurial education can vary significantly according to the national and educational context in question. The range of entrepreneurial education concepts can be organized into three categories (Sánchez et al., 2017:415-416): education about entrepreneurship, education through entrepreneurship and education for entrepreneurship.

The third category has been adopted by the Thematic Working Group on Education for Entrepreneurship of the European Commission (2014A) and the Eurydice Network, which takes the framework definition agreed in Geneva on 18 January 2012 by the main source of authority on the subject: the international working group on entrepreneurial learning, comprising representatives of ETF, GIZ, ILO, UNESCO and UNEVOC.

UNESCO (2008) has followed this line by defining entrepreneurial education as a set of experiences that provide students with the capacity and vision to access and transform all kinds of opportunities using their creativity, initiative, responsibility and attitude towards risk. This skill would go beyond economic action (creation of a company); it is a transversal competence that can help students to anticipate and adapt to change.

The report of the Thematic Working Group on Education for Entrepreneurship of the European Commission (European Commission, 2014a: 6), following UNESCO and the European Training Foundation (2013), defines entrepreneurial education in the following terms:

All forms of education and training (formal, non-formal and informal) which contribute to an entrepreneurial spirit or behaviour, with or without a commercial objective

These definitions make it clear that education for entrepreneurship extends to all educational levels, from childhood education to lifelong professional development.

According to the Recommendation of the European Parliament and of the Council of 18 December 2006 (European Parliament and European Council, 2006:17-18) and the OECD (2012:12), entrepreneurial competence is understood as a set of knowledge, skills, behaviours and attitudes:

- **Knowledge** includes “the ability to identify available opportunities for personal, professional and/or business activities, including ‘bigger picture’ issues that provide the context in which people live and work, such as a broad understanding of the workings of the economy, and the opportunities and challenges facing an employer or organisation” “(Recommendation 2006/962/EC).
- **Skills** are “related to proactive project management (involving, for example the ability to plan, organise, manage, lead and delegate, analyse, communicate, de-brief, evaluate and record), effective representation and negotiation, and the ability to work both as an individual and collaboratively in teams. The ability to judge and identify one’s strengths and weaknesses, and to assess and take risks as and when warranted, is essential”(Recommendation 2006/962/EC).
- **Attitudes** are “characterised by initiative, pro-activity, independence and innovation in personal and social life, as much as at work. It also includes motivation and determination to meet objectives, whether personal goals, or aims held in common with others, including at work” (Recommendation 2006/962/EC).
- **Behaviours** are governed by the criteria of responsibility (which means active and informed participation in the market) and productive creativity (which means production of innovative ideas that help to solve economic and social problems).

SOLUTIONS AND RECOMMENDATIONS

In the international context, there are numerous examples of non-curricular initiatives to support entrepreneurial education; that is, they are promoted by institutions outside the authority responsible for the design, management and coordination of the public education system. In particular, there are a wide variety of non-curricular programmes in Europe aimed at stimulating entrepreneurship, as a result of EU institutions’ intense efforts to promote entrepreneurship over the last three decades.

In short, the European policy for entrepreneurship-building proposes considering entrepreneurship as a valuable social competence that should be protected and reinforced. The basic features of EU policy in relation to implementing a global strategy for entrepreneurial education are as follows:

1. Its main objective is to correct the entrepreneurial deficit that has been detected, in order to prevent the resulting negative consequences for Europe's competitiveness.
2. It follows an action approach to shape the market with measures that promote the improvement of the business environment, rather than actions involving direct financial aid, tax concessions and financial incentives of dubious utility that cause market distortions related to inefficient costs (Hallberg, 2000)
3. The initiatives for education and training in entrepreneurship have mainly relied on widely-differing national-level actions, with the European policy being based around the principle of subsidiarity and the implementation of concerted actions.
4. It proposes educating students to develop their entrepreneurial spirit from an early age.
5. Entrepreneurial education should foster young people's entrepreneurial vocation, but also help them to develop a valid cross-competence that is applicable in all kinds of positions and organizations, and empowers them to "turn ideas into action".
6. It must be integrated into a long-term global perspective that creates a solid and stable framework for entrepreneurship teaching.
7. It must prepare teachers in this field by providing them the required knowledge, aptitudes and attitudes, and equipping them with the appropriate didactic methods. Entrepreneurial approaches to teacher training should include the setting up of training centres for entrepreneurship teachers.
8. The development of entrepreneurial skills requires active and experiential methods that immerse students in real-life practical learning experiences. It is useful for students to gain an early knowledge of the real business world, so that they understand the role of business and its social impact. Learning should be essentially self-driven and active, with elements such as project work, games, simple case studies and visits to local companies.
9. The education for entrepreneurship agenda should extend its actions beyond the educational system to engage companies and the community at large, creating links and cooperative structures. Support systems have, therefore, an important role to play in this regard.

FUTURE RESEARCH DIRECTIONS

Wide differences can be seen between regions and countries in terms of graduates opting for entrepreneurship. Similar variations can be found in the contribution made by education to the development of the necessary skills and knowledge to manage a business, to stimulating the desire to become entrepreneur, to reinforcing entrepreneurial initiative and to acquiring a better understanding of the role of entrepreneurs in society.

A critical point in the debate about the reasons for these differences is how the educational system approaches this matter, and why the training received by the students does not successfully translate into an effective acquisition of the competences that should be incorporated into curricula. The main argument is that higher education is failing to produce graduates with a strong entrepreneurial spirit. In turn, this has generated scepticism about the suitability of universities and/or schools as breeding grounds for future entrepreneurs. However, the empirical evidence on this point is still not conclusive.

In order to tackle the low levels of entrepreneurial knowledge and experience, it is necessary to bolster the acceptance of and the demand for entrepreneurial education. We must clarify the concept (Gibb, 1993) and reinforce the conceptual framework that covers entrepreneurial training initiatives, thus providing effective support for entrepreneurs and policy makers aiming to optimize the investment of resources (Gibb, 2002, Hannon, 2006). At the level of university education, critical issues include deciding who should be offered entrepreneurial education, who should teach it, and how it should be delivered (Hatshorn & Hannon, 2005:616). Matlay (2009) advises considering the expectations of the two primary stakeholders in the process: students and teachers. To that end, both the demand and supply perspectives should be considered. On the demand side, students' perspectives should be examined in order to design and deliver an entrepreneurial education that is effective and tailored to their needs and expectations (Schwartz & Malach-Pines, 2009; Kraaijenbrink et al., 2010). On the supply side, the success of entrepreneurial education initiatives will be defined by the development of curricula designed to meet social needs, the provision of the necessary resources, and the commitment and motivation of trained teachers (Johannisson et al., 2001; Birdhistle et al., 2007; Clergeau & Schieb-Bienfait, 2007). Educational institutions should also update their methods in order to promote the ability to "think outside the box" in problem-solving (Volkmann et al., 2009:15) as well as experiential learning in which knowledge is created through the transformation of experience in a real environment (Formica, 2002).

There is thus an ongoing debate about how the educational system should be restructured in order to incorporate into its methods, contents and organization, the values that form the *raison d'être* of the entrepreneur (responsibility, recognition, creativity, initiative), and also to teach the knowledge and skills necessary to stimulate entrepreneurial initiatives. Future research should be aimed at consolidating an institutional and curricular design that includes a focus on entrepreneurial spirit, in order to strengthen economic, business and financial education.

CONCLUSION

The literature contains extensive analysis of the genesis of the entrepreneurial process. The first generation of studies was oriented at identifying the specific psychological and demographic traits of the individuals that are most likely to create a company. This approach has generated few useful results because it has failed to find a universal pattern, and it has not empirically established a relationship between the differential characteristics of the entrepreneur and the subsequent success of the start-up. These days, it is generally accepted that psychological and demographic traits are poor predictors of entrepreneurship.

A new approach comes from the so-called models of entrepreneurial intention, which predict that exogenous variables do not directly influence entrepreneurial behaviour; rather they affect the determining factors for such behaviour. According to the intention-based models, the key issue is the variables that trigger entrepreneurial intention. Three aspects that shape entrepreneurial attitude have been identified: the desirability of a behaviour (based on the beliefs of the individual), its feasibility (possibility of control over the behaviour) and the perceived social norms.

The intention-based models thus assume that the entrepreneur can be trained through an education that instils the attitudes required to transform perceived opportunities into viable business ideas. Proponents of this argument reject the idea that genetics play a role in entrepreneurial development and that entrepreneurial talent depends on innate personal traits. There is a wide range of literature explaining young people's entrepreneurial intentions and their professional entrepreneurial skills as a result of their

immersion in a participatory professional training programme. It has even been argued that the core qualities of the entrepreneur, such as creativity and innovative ability, can be learned and encouraged.

This belief has prompted multiple national and international initiatives aimed at stimulating entrepreneurial education. However, these initiatives have not yielded the desired results. There are many regulatory and institutional reasons why graduates decide not to get involved in the creation of a new company.

But above all, the key issue is how the educational system has designed the curricular content to address this question, as it may not ensure that the training received by students is being translated into an effective acquisition of the relevant competences. The empirical evidence is not conclusive, but it seems to indicate that such teaching is not successfully producing entrepreneurial graduates, and that neither university nor schools are currently effective breeding grounds for future entrepreneurs.

KEY TERMS AND DEFINITIONS

Education About Entrepreneurship: Consists of teaching general theoretical knowledge about concepts related to entrepreneurship, but does not involve practical experiences that consolidate learning and help shape learners' attitudes.

Education for Entrepreneurship: Theoretical-practical approach to providing entrepreneurship knowledge and skills aimed at influencing the development of entrepreneurial attitudes and behaviours.

Education Through Entrepreneurship: Action-based, experiential teaching method in which potential entrepreneurs learn directly through their immersion in entrepreneurial experiences.

Entrepreneurial: Competences: A set of knowledge, skills, behaviours, and attitudes that allow the identification of existing opportunities for personal, professional, and commercial activities, and enable their transformation into viable entrepreneurial ideas.

Entrepreneurial: Education: Type of education and training that helps develop the entrepreneurial spirit, competences and behaviour, regardless of whether or not they are aimed at a commercial objective.

Entrepreneurial: Spirit: Ability to transform creative ideas into entrepreneurial actions. It is related to creativity, innovation and risk-taking, as well as the ability to plan and manage projects to achieve goals.

Entrepreneurship: An attitude that reflects an individual's motivation and capability, whether independently or within an organization, when identifying and seizing an opportunity in order to produce new economic value or achieve success.

Designing the Future of Romanian Women Entrepreneurship: Fight and Flight

INTRODUCTION

According to the Organization for Economic Cooperation and Development (OECD), the contribution of women in entrepreneurial activities is not well known mainly due to the lack of valid and reliable data about male-female variable in entrepreneurship. In order to develop effective policies for improving equality between men and women in entrepreneurship it is necessary to collect detailed data which could be compared at an international scale (OECD, 2005).

The relatively recent interest of women for business has been observed by other specialists who have found through the studies they conducted the following fact the increase in the number of women entrepreneurs in industrial countries is recent. Before 1970 women entrepreneurs were rare. Since then, their growth has been remarkable (Coughlin & Thomas, 2002; Hallam & Zanella, 2017).

In what concerns the evolution of women entrepreneurs in the European Union, Parker (2004) mentions the fact that the percentage of self-employed in this region varies considerably from about 20% in the UK, Ireland and Sweden to 40% in Belgium and Portugal. Following the purpose of an overview on female entrepreneurship in Romania, and implicitly on females interested in creating and developing a business, a presentation of certain issues is required, such as the country's total population, the number of females, the number of women entrepreneurs (Dorobat & Topan, 2015; Gundry & Ben-Yoseph, 1998).

Regarding the number of females interested in owning their own business, developing and achieving its performance it can be said that in Romania there are over 500,000 women entrepreneurs, representing 34% of the shareholders or domestic companies (Pocol & Moldovan-Teselios, 2014).

BACKGROUND

The literature presents numerous definitions, features and typologies of entrepreneurship and entrepreneurs, and the study of entrepreneurship, in general, and of women entrepreneurship, in particular, is one of the reasons that have determined a whole series of researchers to allocate time and energy to better know this domain, to uncover new information, and to go deeper into the older knowledge (Afrin, 1999; Goby & Erogul, 2011; Kerr, 2017; Raghuram & Hardill, 1998; Savoiu, 2014).

According to some researchers (Fitz-Koch et al., 2017; Hallam et al., 2016; Landig, 2011; Marlow & Wynarczyk, 2010), women still form the most underrepresented group in entrepreneurship, and among the reasons why the number of women entrepreneurs has been reduced over time includes: social and cultural influences, education and options related to career, but also the lack of self-confidence, perceptions regarding the traditional place of women, family responsibilities, motivation and attitudes of women regarding risk. After starting the business, a number of factors such as: the lack of/the limited access to human capital and financial barriers related to network information and access to care, and also the concern regarding women oscillation between family and career have influenced women's involvement in entrepreneurship (Farmer et al., 2011; McGowan et al., 2012; Ruderman et al., 2002).

A study conducted by the Centre for Entrepreneurship and Business Research – CEBR (Driga & Lafuente Gonzáles, 2009), on female entrepreneurship in Romania that had 626 participants of which 378 (60%) men and 248 (40%) women revealed that in Romania, the male entrepreneurship prevails (the number of men involved in entrepreneurial activities exceeding that of women in all geographic regions of the country). The research also reveals that the proportion of potential women entrepreneurs exceeds that of men, that means that more women than men are involved in the actual start of a business in all regions except Western areas (Arad, Caras- Severin, Hunedoara and Timis), and in the South (Arges, Calarasi, Dâmbovița, Giurgiu, Prahova, Virginia), where the number of potential men entrepreneurs, outnumber the women. For the group of new entrepreneurs (entrepreneurs who have started a business in the past two years), the situation is as follows: the percentage of men entrepreneurs exceeds that of women entrepreneurs in the capital, the North-West (Bihor, Bistrita-Nasaud, Cluj, Maramures, Satu Mare and Salaj), the North- East of the country and in the South, and the women entrepreneurs exceeds the proportion of men entrepreneurs in central Romania (Alba, Brasov, Covasna, Harghita, Mures and Sibiu), in the West, the South-East and the South-West (Dolj, Gorj, Mehedinti, Valcea and Oltenia).

Regarding age, it can be said that in what concerns entrepreneurs, be they prospective or active, women have a slightly more advanced age than men. Thus, women who are potential entrepreneurs have an average age of nearly 42, while men in this group have a mean age of 41.

Regarding work experience, it can be said that women have on average more work experience than men. Thus, previous work experience, on average, is three years longer for potential women entrepreneurs, compared to their male counterparts (15 years versus 12 years for men), and women entrepreneurs who have started a business in the last two years have, on average, an extra year of work experience than men (10 years for women and 9 years for male entrepreneurs).

Among the motivations of women entrepreneurs in Romania we can mention: the desire to be their own boss, the desire to have their own business, finding business opportunities, the desire to improve quality of life, the desire to make a contribution to society, the desire for social status, the desire to make money, the motivation to pay less taxes, the desire to not be unemployed, the desire to follow the family tradition, the admiration for other entrepreneurs.

Regarding the profile of successful women entrepreneurs in our country, some authors (Baughn et al., 2006; Dima et al., 2011; Zellweger et al., 2012) claim that in Romania, the general idea is that a

successful woman is one who can excel in different fields, they put career first, but do not neglect their family. Also, she must be financially independent, self-confident, to assert herself and achieve success without losing femininity.

RESEARCH METHODOLOGY

An overview on women's entrepreneurship in Romania can be shaped by conducting a qualitative study that could bring together the defining profile of women entrepreneurs in Romania. For the purpose of this study that aimed at identifying the main issues related to female entrepreneurship (motivations, resources, support groups, obstacles, etc.) a direct research - based survey was used.

The study was considered a sample of 110 women entrepreneurs from South - Muntenia region of Romania that includes seven counties. The response rate was 55%.

The questionnaire used in the survey included 21 questions, divided into six sections, and responses collected using the questionnaires allowed the calculation of statistical indicators for this study, namely: the mean, median, mode, standard deviation/standard error, variance, the amplitude of the variance, the minimum, the maximum, the sum of all observations, the asymmetry coefficient Skewness, the vaulting coefficient Kurtosis and the calculation of quartiles.

Section 1 includes questions 1-2 and aims to identify the profile of women entrepreneurs interviewed, mainly to determine their age and profession.

Section 2 contains questions 3-4, which refer to the characteristics of the activities of the individuals interviewed in the entities they lead: activities mainly carried out within the company, the training they deem necessary.

Section 3 includes questions 5-9 and investigates the factors that contributed to the decision to establish a firm: the reasons that led to the specific entrepreneurial career choice, the reasons that led to the renunciation regarding the earlier profession, the choice of a company's business domain, personal qualities which, according to women entrepreneurs, have favored the creation and development of the enterprise, the support groups.

Section 4 contains question 10 to 12 and examines both the difficulties faced by women entrepreneurs and also the means to overcome them: the major difficulties encountered during the creation of the enterprise and its development, the main ways of overcoming difficulties, how to obtain the funding sources.

Section 5 is represented by questions 13 to 16 and explores the future of companies led by women entrepreneurs starting from the results so far: the factors that contributed to the smooth running of the company, anticipating future obstacles, the prediction of future opportunities, ways of overcoming obstacles.

Section 6 contains questions 17 to 21 and analyses the opinion of women entrepreneurs regarding women entrepreneurship both in Romania and in other countries, and also the perception of women regarding the labor market.

The questionnaire was applied directly or through e-mail on 200 women entrepreneurs in the South-Muntenia Region, the response rate was 55%. There were 110 completed questionnaires out of 200 submitted.

Responses were collected using questionnaires processed using the Scientific Package for Social Sciences (SPSS) 17.0 and the making of the database structure was achieved by defining variables in Variable View. It is also important to note that all completed questionnaires were checked in terms of background completeness and usefulness of data and using the statistical program previously mentioned,

data analysis was materialized through frequency tables and histograms for each item, and the centralization of all items.

In addition to the related tables and histograms, data analysis led to an emphasis of statistical indicators for this study, namely: the mean, median, mode, standard deviation/standard error, variance, amplitude of variance, minimum, maximum, the sum of all observations, the coefficient of asymmetry Skewness, the coefficient of vaulting Kurtosis and the calculation of quartiles.

The fundamental/main objective of this study is to identify key issues related to female entrepreneurship in Romania and in order to find relevant answers a series of secondary objectives of the research were established, as follows:

- O₁: Identifying the reasons that determine women to choose an entrepreneurial career.
- O₂: Establishing the necessary resources for the good of the business.
- O₃: Establishing support groups, the main actors involved in supporting and encouraging women to take the entrepreneurial function.
- O₄: Identifying barriers that hinder or could prevent women to run a business and ways of overcoming difficulties.

Regarding the link between the four mentioned objectives of this research on female entrepreneurship and the twenty-one closed questions in the questionnaire included in the survey, the following statements can be made:

- § To the first research objective, O₁: Identifying the reasons prompting women to choose entrepreneurial careers, corresponds to question number 5 of the questionnaire.
- § To the second objective of this study, O₂: Establishing the necessary resources for the good of the business, the statement number 12 of the questionnaire, corresponds.
- § To the third objective of the research, O₃: Establishing support groups, the main actors involved in supporting and encouraging women to take the entrepreneurial function, the following interrogative sentences in the questionnaire: 9, 12, 21, correspond.
- § To the final research objective, O₄: Identifying the barriers that hinder or prevent women to run a business and ways of overcoming difficulties, the following questions correspond: 10, 11, 15, 16 and 20.

The research was based on assumptions that resulted both from theoretical research in the field as well as from discussions with entrepreneurs in general and with women entrepreneurs in particular. Thus, in order to achieve the research objectives the following hypotheses were considered:

- H₁: The main reason underlying the entrepreneurial career choice is economic.
- H₂: The main source of finance business financing is represented by personal savings.
- H₃: The main difficulty faced by women entrepreneurs is competition.
- H₄: The family is the primary support group of women in their choice regarding an entrepreneurial career.

SOLUTIONS AND RECOMMENDATIONS

Following the realization of this study, it has been noticed that regarding item 5, “the reasons that have determined the choice of the entrepreneurial career” dominant is the category of women entrepreneurs

Table 1. Calculation table for the testing of hypotheses

The hypotheses	N	Mean	Std. Deviation	Std. Error Mean

who have claimed that the economic motives constituted their main impulse when they started their business (a frequency of 48 respondents out of 110 interviewees, which represents 43.6% out of the total of the respondents).

The research found that the four hypotheses of the study were confirmed (see Table 1), contributing to the scientific funding of the portrait of the women entrepreneurs in Romania.

The results showed that all the other answer variants were chosen by less than a third of the women entrepreneurs interviewed, actually it has been noticed that those who wanted to put into practice their

ideas recorded frequency of 22 out of 110 respondents, namely a weight of 20%, those that did not want to be subordinated present a frequency of 18 out of the total of the interviewees (16.4%), the women entrepreneur who claimed that the main factor in the choice of their career is the lack of a better alternative recorded a frequency of 15 out of 110 subjects (13.6%), and on the last position come the women entrepreneurs who mentioned other considerations. Namely, 7 people out of 110, representing a percentage of 6.4%, declared that the motives for choosing the entrepreneurial career were represented by: the desire of professional accomplishment, the lack of satisfaction caused by the previous job.

The main indicators (average, mean, module, standard deviation, variant, amplitude of the variant, minimum, maximum, sum of all the observations, skewness coefficient, kurtosis coefficient, quartiles) specific for the fifth item, "the motives that determined the choice of the entrepreneurial career", highlight the fact that calculated for the 110 recordings, all valid, the skewness coefficients 0.486, which indicates the fact that the distributions asymmetric to the right, and the kurtosis coefficient has the value of -1.217. The ways the capital needed to start the business was obtained allowed the delimitation of the following categories: personal savings, selling a personal asset, loan from friends, bank loan.

The study carried out highlights that most of the women entrepreneur (72.7%) used their own savings, and, at the opposite pole, only 3.6% of the subjects considered that selling a personal asset or using a loan from friends are optimal ways of obtaining the capital needed to start the enterprise.

The relatively low weight of the subjects that used bank loans (20%) was determined, in general, by their sufficient development of the financial and monetary market and especially by the difficulties encountered in the relation with the bank.

The difficulties encountered during the activity allowed the delimitation of the following categories: lack of leadership experience, lack of marketing knowledge, lack of accounting knowledge, lack/ high cost of capital, lack/ high cost of qualified personnel, competition, low demand for the respective product/ service, bureaucracy, discrimination, socio-cultural influences, yet the subjects had the possibility to also mention other categories if they have considered that the previously enumerated variants do not correspond to their situation.

Following the study, it was possible to notice that the distribution of the women entrepreneurs according to the difficulties encountered is somewhat surprising. No subject has complained of lack of leadership experience or of the sociocultural influences. The research also highlighted the fact that half (50%) of the women entrepreneurs consider competition as a main obstacle, while 12.7% of the subjects consider bureaucracy to be a real difficulty and 11.8% claim that the main obstacle is discrimination. The lack/ high cost of capital, lack/ high cost of qualified personnel and the excessive taxation of the economic agents are considered obstacles by a low percentage of the interviewees (5.5% each).

At the same time, one can say that on the last positions come factors such as: lack of accounting knowledge, low demand for the respective product/ service (3.6% each) and lack of marketing knowledge (1.8%). The main activity in which women entrepreneurs work is trade, product sales being mentioned by 57 respondents, representing 51.8% of the women entrepreneurs surveyed.

In order to highlight the support groups, the people with a favorable impact on the activity of the women entrepreneurs, the following answer variants were proposed: family, friends, specialists, but the subjects were also given the possibility to mention other categories if they considered that the variants enumerate previously do not correspond to their situation.

On the distribution of the women entrepreneurs according to their support groups, one can say that it is remarkable that a significant proportion of the interviewees (92 subjects out of 110, namely 83.6%) have been supported in their entrepreneurial career by their family, while a relatively small percentage of the respondents (10%) have declared that the specialists (economists, lawyers) have represented the main

support group in their activity, and on the last position come the subjects who have declared that a favorable role in the creation and development of their business came from the support from friends (6.4%).

Regarding the calculation of the main indicators pertaining to this item one can say that it has been noticed that calculated for the 110 recordings, all of them valid, the skewness coefficient is 2.186, which indicates the fact that the distribution is asymmetric to the right, the kurtosis coefficient has the value 3.196, namely the distribution is leptokurtic/ has a sharp peak.

FUTURE RESEARCH DIRECTIONS

Through the goals set, this chapter has touched its target. The presented and analyzed issues are a synthesized part of the vast amount of information that has been developed by the authors to create the framework for understanding Romanian women entrepreneurship. Therefore, there are new directions of future research such as:

- § The analysis of the influence of women entrepreneurship on business and the impact of sustainable development on the mentioned notions;
- § Since the sample of the study was selected from Romania, this study can provide precious data for those interested in studying this region, but a kind of vigilance must be kept in mind when generalizing the results to other countries.
- § Analyzing and interpreting the dilemma situations faced by women entrepreneurship from the former socialist countries that have not been analyzed in this chapter.

CONCLUSION

Women entrepreneurship as a science, practice and as art designates the involvement of women in the creation and development of a business and its history began relatively recently. Due to the positive influence exerted by entrepreneurship in general, and especially by women entrepreneurship, on the stimulation of the economy and on the general progress of the society, it is advisable that the domain of women entrepreneurship and the women's involvement in business should be considered and used for what they really are, a truly valuable resource.

The study wanted to identify relevant aspects of females in specific business practices and focused its attention both on the main traits of women entrepreneurs, the key qualities needed in this area and also on the obstacles encountered, on the gender barriers subjects encountered along their entrepreneurial career, their perceptions regarding their business and how they want their business to evolve in the future.

The research results revealed a profile of female entrepreneurs aged between 31 and 50, an age group which combines some of the characteristics of young age (optimism, initiative, dynamism) with specific strengths of the mature age (experience and maturity in thinking). Usually a female entrepreneur has a university diploma, mainly in the economic field and believes she needs legal training, but does not complain about the lack of management experience, marketing or accounting knowledge.

The study also shows an accomplished female entrepreneur who possesses a strong sense of entrepreneurship, working mainly in trade, she believes that women are discriminated slightly in the labor market, claims that at the basis of their entrepreneurial career there have been economic reasons and she is supported by her family in her entrepreneurship career.

The study realized brings to light a woman entrepreneur who claims that at the basis of their entrepreneurial career there have been economic reasons, the too small salary being the main reason for giving up the previous job. She relied on her own savings to start a business; she is supported by her family in her entrepreneurship career and considers the competitors as the main threat for the business she is running.

An important role for the functioning of entrepreneurship in general and female entrepreneurship in particular, and also for encouraging and creating favorable conditions for the business, is played by the legal and institutional framework. In other words, awareness regarding women's entrepreneurship not only for economic growth but also for the overall progress of society has led to the development of certain laws, as well as bodies, organizations, institutions and programs involved in supporting the business sector, in promoting and stimulating the women's entrepreneurship and also the entrepreneurship in general, in this sense a series of activities that fall in this category could be mentioned: providing advice and assistance in the organization of courses, facilitating the connection to domestic and foreign networks of similar business organizations etc.

The need to support women is not only important for business development, the labor market and the economic environment in general, but also to improve all areas of activity. Although a large proportion of respondents view more opportunities for the future in terms of improving the legal system and the granting of tax incentives and less by the emergence of business opportunities, there are Romanian women entrepreneur who believe that a number of factors are the real determinants of family business development (the possibility to access EU funds, the emergence of new market counterparties and the possibility of expanding the business, but also to diversify products and services).

The importance of sustaining female entrepreneurs is supported also by specialists (Alsos et al., 2014; Tiwari & Tiwari, 2007; Wiklund et al., 2012) who say that women are the core of a nation. They are the true builders and modelers of the destiny of a nation. Position and status of women in any society are indicators of civilization and progress of that specific society.

KEY TERMS AND DEFINITIONS

Entrepreneurship: A person who takes risks, because buying products with a certain price and sells them to one another, so deploying a risky activity.

Motivation: Is a problem of temperament: on one hand, we will always meet individuals that are more passionate than others, who are more dedicated to their work, and on the other hand, there are methods likely to contribute to changes in attitude towards work, decisive, both for the success of the individuals in organizations, and for the organization's success on the market..

Organization: A system, which includes employers and employees aiming at achieving common objectives.

Personality: The totality of individual's character traits, temperament, education, and behavior.

INTRODUCTION

The economy of the digital age is an economy, based on collection and use of knowledge. Significant gains, the necessary breakthroughs over the past decades, is understanding of the relationship between knowledge and growth, on the one hand, and entrepreneurship and growth, on the other one. Also one can find research results shown how entrepreneurship, innovation and knowledge are interrelated. In the same time, deep understanding of a connection between all these variables - knowledge, innovation, entrepreneurship and growth - does not exist. The relationship between the variables is very complex and depends on forces that can simultaneously influence all of them; at least, partially. Therefore, the relationship between the microeconomic origin of growth and the macroeconomic state is still too unobvious to cover the entire width of these complex and overlapping variables.

The state support of entrepreneurship acquires special features in the digital economy and should be based on several principles.

1. More does not mean better. Financing (investing, subsidizing, etc.) should have a strictly adjusted focus and volume. Naturally, firms, focused on innovation, on deepening existing knowledge and their practical application, should be in the priority. However, their “overfinancing” may be, in the best case, senseless. *The relationship between investments and results is not linear; it must be considered carefully and taken into account.*
2. The digital age is characterized by the availability of huge amounts of information (so called “big data”), its storage, searching and analytic tools (Chang et al., 2008; Ramzan et al., 2018). Any effective management decision should be based on analysis of *all* available data on the subject. In the case of innovation economic activity, such data includes the history of the field in aspects both of innovative ideas (previous successful/unsuccessful similar business projects) and of project performers (open personal data of participating people/firms their economic success in the past,

DOI: 10.4018/978-1-7998-3473-1.ch101

- etc.) *Collection of sufficiently complete information, related to the specific business project, is one of the critical components of the decision-making process concerning the project support.*
3. Analysis of large amounts of information that have become available only recently has been one of the challenges of our time. The human brain, in general, is not capable of solving such problems and needs substantial “algorithmic” support. As a minimal basement, these are the standard data mining and graphical data representation methods. However, for effective management, this is usually not enough. Algorithms of “artificial intelligence” can come to the rescue; first of all, it is methods of machine learning (neural networks, genetic algorithms, etc.). *Without computer algorithms of “artificial intelligence”, appropriately “trained”, effective processing big data is impossible.*
 4. The task of “training” of artificial intelligence systems is a special problem. The most natural and “economising” way is the creation of universal “avatars”, focused on solving a wide range of business plan evaluation tasks and trained gradually during the step-by-step use for a number projects. *Avatars should become the core of “intelligent expert systems”, which should replace the traditional expert systems.*
 5. “Intelligent” avatars, working with large data sets, face the problem of composing used information, which is constantly growing set (Deissenberg et al., 2008; Kohler et al., 2009). In addition, if there is a “population” of avatars, which are focused on solving slightly different tasks, they can “exchange” by their individual “experience”. The solution of both the problems can be based on the blockchain technologies. *The blockchain organization of distributed data storage creates a flexible and efficient knowledge base about business projects, used by the avatars.*
 6. Considering the “intellectual expert system” as a dynamic, constantly developing system, one can speak of the underlying computer “imitation model”, which has a special theoretical and practical value. External information sources, the blockchain-based knowledge base, the avatar population, external actors (people-users) and a software environment, uniting all these elements, are in constant nontrivial interaction, the result of which cannot be predicted theoretically, but can be obtained in a course of computer simulation. *In addition to being used directly for the project evaluation, the simulation model can be used to solve a much wider range of tasks: forecasting (of final budgets of projects, their possible profit, etc.); risk assessment; determining projects’ and their performers’ rating; calculating parameters of an “ideal” project, etc.*
 7. There is a significant variation of conditions, prevailing at the time, in different countries and even regions of the same country. There is an ontological problem of distinguishing “common” and “individual” features of environment, when analyzing projects and making decisions. Probably, *each avatar should be targeted to a specific region; at the same time, the entire avatar population should use a joint blockchain base.*

Below these principles are considered in more detail. Mainly, it will be discussed about a single avatar; study of avatar populations is planned as a next step of the research. When this is essential, the Republic of Armenia will be used as a “model” region.

The authors in this chapter show the essence, dignity, current state and development prospects of avatar-based management using blockchain technology for improving implementation of economic solutions in the framework as help system of entrepreneurs of sharing economy. The authors of the chapter set out to avoid examining the avatars-based model for policy advice, but to try to assess the merits, identify the model as a new basis for policy advice based mainly on work and experience as part of a recently completed project “Triple H Avatar an Avatar-based Software Platform for HHH University, Sydney,

Australia which was carried out 2008-2018” (Mkrttchian et al., 2016). The main goal of this project is to create such a model based on avatars where there is a link between macro and micro levels that provides a single platform for solving problems in various areas of the digital economic system that is designed to assist entrepreneurs. This project was the first to create such a model implementation that allows you to scale simulations for a large number of economic avatars and provide graphical user interfaces that allow researchers at the user level not familiar with the technical details of the implementation to implement for the design of individual parts of the model, engineering and economic experiments and analysis of modeling results for the system of assistance to entrepreneurs.

BACKGROUND

In conditions of the digital economy, dynamic processes (their theory, models, nodes, blocks), although they have been understood quite deeply, still do not take into account a private influence of the entrepreneur, who acts as an independent innovator and has his direct impact on the dynamics of economic performance. Expert knowledge in the form of accumulated human and/or physical capital, can no longer explain the significance of economic development. Since Adam Smith also proposed the introduction of innovations and entrepreneur for profitable transformation of the above resources (Andersson & Tollison, 1982).

The phenomenon of “development” in the digital economy has shown that there is a non-standard, adaptive-individual relationship between knowledge, innovation and entrepreneurship. These links are becoming more noticeable in the dynamics of economic development in the process of digitalization of the economy. The current view is that the introduction of innovations in the field of knowledge is always a linear process related to activities, research and development. Our research (Mkrttchian et al., 2016) has showed that many various processes, such as learning, cognitive abilities, network interaction, combinatorial ideas, etc., limit public knowledge, turning the whole process of innovation into a non-linear process. It turns out that uncertainty, search and experiments are key elements of the innovation process. It has been shown that activities to create knowledge about entrepreneurs and small firms are spreading across a range of different functional areas. Failure to comply with these aspects means that several studies ignore a significant part of the creation of knowledge relevant to innovation and economic growth. This requires a new approach, thus open software products, available to all. But at the same time there is no guarantee that new knowledge with commercial potential will immediately be transformed into entrepreneurial initiatives and these effects are based on these knowledge may not appear at all or appear with a delay (Mkrttchian et al., 2016). It means that deep, case-oriented methods of estimation and modeling of the innovative entrepreneurship development should be proposed.

Extensive literature is devoted to the study of the prospects and effectiveness of business projects (and, in particular, innovative start-ups). A review of publications, devoted to this topic with a focus on the introduction of current scientific achievements, can be found in the articles (Natalichio et al., 2017; Spender et al., 2017).. Most of the proposed methods are not focused on the use of large data tables, but they contain interesting approaches, sometimes implemented in the form of ready-made algorithms (Cegarra et al., 2015; Gambal et al., 2018; Sjödin et al., 2018; West, Bogers, 2014). The ideas of this field of knowledge are the basis of the logic of the functioning of avatars.

Development of computer intelligent agents (which can be called as avatars in the context) is a special branch of computer science that has been booming in recent years (Dawid & Fagiolo, 2008; Ferber, 1999). Avatar-based approach to decision-making process in economy and politics became popular last

years (Arifovic et al., 2010; Dawid & Fagiolo, 2008; LeBaron & Winker, 2008). The specific inputs/outputs of the avatar and its specification are determined by a specific application area; for the considering problem, the basic model was proposed in (Mkrttchian, 2013). It is so called “Triple H Avatars”.

The blockchain method of creating and maintaining distributed databases has spread widely due to the recent popularity of crypto currency computer systems. However, the potential of this approach are much higher; at present it is gaining popularity for elaboration of “self-developing” information systems of various profiles (Maiyya et al, 2018; Mohan, 2017). The use of intelligent avatars is based on semantic analysis of distributed information is analyzed, so we need in blockchain-*knowledge* base, not just data base. Knowledge Base is a separate and also rapidly developing part of the computer science (Krishna, 1992; Natalicchio et al, 2017). Its ideas were used for the development of the basic avatar model, and will be actively used to improve the model in the future.

Our research (Mkrttchian & Aleshina, 2017) is the first to identify the application potential of blockchain technology to sliding mode in intellectual control and communication, for help the technological challenges and created tools. The intelligent avatar is based on a trigger switch that allows you to connect interorganizational processes to web services and implement internal processes. These triggers serve as a bridge between the block chain and enterprise applications. This concept provides the ability to implement intelligent control and built-in control at certain points in the process where it is desirable and possible (Mkrttchian, et al, 2016). The engineering realization of this advance is still nascent at this stage, although some early efforts can be found in our previous works. For example, intelligent visualization techniques that enforce a process execution in a trustworthy way can be generated from sliding mode process models (Mkrttchian, and Aleshina, 2017).

Multi-agent models and methods of computer simulation are another trend in computer science development (Ferber, 1999; Gilbert & Troitzsch, 2005). Its results are also part of the considered technique. It is useful, first of all, in solving the following problems: forming an “environment” algorithm, which unites a set of agents into a system; organization of an effective computational process, including the choice of a software tools; and planning simulation experiments to select rational process parameters and to identify possible key development scenarios.

The first steps towards elaborating the described computer systems for analyzing innovative business plans and making managerial decisions were implemented in the works of the authors (Bershadsky et al., 2018; Mkrttchian, 2013, 2015; Mkrttchian & Aleshina, 2017).

MAIN FOCUS OF THE CHAPTER

Issues, Controversies, Problems

The main objective of the proposed approach has already been described above: it is support of decision-making process concerning innovative startups by special software. The main issue is the possibility of developing intelligent information systems (Weikum & Vossen, 2002), that can significantly improve the state and regional policies in the field of innovation support. The idea of using ICT in the claimed area is evident; however, there are countless ways of its implementation. The describing approach is an attempt to bring to the solution several modern methods from the most advanced sections of computer science. Possible objections to such an approach could be a statement about the excessive complexity of the method, which leads to: a) too expensive and time-consuming development of the information system; b) its expensive and unreliable support; c) problems with effective use of the system because

of difficulty understanding by users of system's abilities and methods of its control. It can be a problem, but it is possible to give examples of successful development and operation of systems of not less complexity. In any case, the observed explosive development of artificial intelligence systems makes them increasingly accessible; and the development of the theoretical base takes considerable time and, naturally, must precede practical implementation. In terms of user friendliness of the system, it is clear that conducting theoretical studies, it is necessary to constantly keep in mind the practical specificity of the problem and the effective ways of system's practical use.

The practical use can be quite different for different places and time moments (Belk, 2007). Theoretical achievements and empirical studies seem to confirm the view that the processes of generating knowledge, innovation and entrepreneurship are localized processes. Nevertheless, no matter what flows of knowledge are largely limited in space, one can observe how knowledge, innovation and entrepreneurial initiatives are exchanged between functional urban areas and even countries. Thus, despite the fact that the regions are characterized by different internal economic and infrastructure networks, they are also connected by a multitude of such networks. Obviously, there is an important interaction between localized processes of knowledge generation, innovation and entrepreneurship, but at present there is practically no understanding of the relative importance of interregional and international networks. An increasingly global knowledge base serves to expand and diversify the local knowledge base, i.e., what was invented by "local noise and global pipelines".

Collected data and computer simulation can reflect features of different local situations. The intellectual tradition mentioned above and similar observations on the role of entrepreneurship in the success of the city on the example of the Republic of Armenia showed that the shortage of entrepreneurs in mining areas reflected its historical concentration in industry, which had a significant return on scale and potentially displaced more entrepreneurial activity. We expect that this evaluation of entrepreneurship is associated with both static factors (for example, with access to investment, and with financial capital for new enterprises) and dynamic factors (for example, the transfer of skills and attitudes from parents to children). In contrast, there was a vivid impulse of entrepreneurship, coming down from the city's early work in the decentralized mining industry, and we can argue that this industrial genealogy helped explain why one region grows faster than another neighboring one. Although his analysis pointed to the strength of local cultures of entrepreneurship, we refrain from making any strong policy recommendations related to this conclusion.

Moving from entrepreneurship to innovation, the relationship between innovation and efficiency of the city was focused on the model. This model especially explains the economy of cities, why cities grow or shrink, and also the movement of industries in different cities. The premise of the model is that the location of industries in cities is determined by where past breakthrough inventions occurred. This conceptual model creates models that fit well with data: for example, it predicts that industries will move around cities much faster than cities will move up and down the city size distribution.

Carefully study of features of innovation in the "cities of companies", in which one large firm dominates, shows that these large firms often become insular in their innovations, relying more on past experience of the company and less studying their efforts in the field of research and development. Based on the consideration, we can state that the combination of large and small firms provides the most productive environment for innovation. The study showed that the optimal mixture for patenting growth in the local area includes at least one large innovative firm, but also a sufficient mass of many small innovative firms. This mixture best reflects the benefits of innovation that come from large firms, while preserving fertile ground for new start-ups, often created by former employees of operating firms. The existing work on entrepreneurship and local innovation does not imply any natural local policy. This,

however, points to the power of small start-ups, which can collectively shape the economic destiny of the region. The study showed that in the two study areas of the Republic of Armenia there was a subsequent decline in employment. However, today, one area is flourishing, unlike another, because of the large number of local entrepreneurs, some of whom grew up in the city, and others were brought into the city from outside. The key issue for local innovation policy is whether there is something that can be done to introduce more of this local business. Clusters are seen as a tool to advance this goal, and we turn to empirical data on economic clustering.

The case for cluster policy depends on the existence of strong inter-firm side effects, which naturally generate clusters and justify a spatially oriented business policy. In order for these policies to make sense, these side effects should demonstrate an increase in returns to scale (that is, 200 entrepreneurs generate more than twice as many secondary effects from 100 entrepreneurs) or are disproportionately distributed among members of a certain industrial sector. That is, even if entrepreneurs generate secondary effects, it makes sense to group these entrepreneurs if these side effects either work non-linearly in local areas, or if only entrepreneurs benefit from clustering with each other. The clustering can represent side effects between companies or the uneven distribution of production factors throughout the space. Some branches of the mining industry of the Republic of Armenia require specialized infrastructure, including physical highways and information highways. Governments have long taken on the role of supporting the provision of infrastructure, although economists and academics have discussed the merits of financing user fees. The need for a specialized infrastructure increases the value of clustering. In contrast, industry groups that do not need specific technologies provided by governments will have fewer advantages from clustering. Even if business clusters are good for local growth, it is less clear that cities or states have the ability to generate these clusters that are the same both at the local level and at the national and global levels.

Solutions and Recommendations

Let us dwell first on the main specific solutions and recommendations concerning the algorithmic support of the process. The virtual research process can be illustrated by the diagram (Mkrttchian, 2015) in the Figure 1.

Figure 1. A scheme of interaction of the components of the avatar-based decision-making system

It is proposed to use the avatars with associated neuronal networks. As a first approximation, their inputs are forming from the information about: previous similar innovative start-ups; open data about the project executors; previous estimations and decisions about the project, particularly, from other avatars and real moderators and researchers. Their outputs are evaluations of perspectives of the project and recommendations (in different forms) concerning its support. In particular, they create, use and develop a blockchain knowledge base about all previous evaluations, recommendations and actions. The blockchain base is a main source for training the avatars' neural networks: previously generated information is compared with further collected information, and neural networks' parameters are corrected.

A special avatar output is an interface to other actors of the process, particularly, human researchers and moderators. It is part of the intelligent expert system, which includes elements of traditional expert system. The avatars contribute to the process, providing processed information, but final decisions are made by human actors. These solutions are also used to train the avatars and are written to the blockchain. The avatar continues to collect information on the progress of the supported project, which is included in the blockchain step-by-step. It is such indications as the project's effectiveness, its compliance with the originally stated parameters and so on. The neural networks will be gradually adjusted, and further all the gathered information will influence the subsequent recommendations of the avatars.

Although the method is not realized completely, some preliminary consideration of the process can be discussed. It was shown that the process of economic development in the modern digital economy can be divided into three clearly separate stages. The first stage involves the technical discovery of new things or new ways of doing things, such as invention. At the next stage, innovation occurs, that is, the successful commercialization of a new product or service, stemming from technical discoveries or, more generally, a new combination of knowledge (new and old). The final step in this three-step process - imitation - involves more general adoption and distribution of new products or processes to markets (Mkrttchian & Belyanina, 2018). The most common measure for the use of knowledge and innovation is expenditure on patents. To manage open software resources it is quite reasonable to use digital avatars (Mkrttchian et al., 2016).

Open source software has long become a ubiquitous industrial production and business. There is, for example, a tremendous amount and variety of open-source software components and third-party components that arise in every software development environment in the world. With proper use and management, these components are a huge source of energy to accelerate innovation in the digital economy. But in such successes of digital transformations there are key components. One of them is a formalized ontology, the development of which in the world today is paid the most attention. Therefore, the authors on specific examples tried to show the digital transformations in Armenia and their moving hidden springs. Because the digital economy is nothing more than the effects of additional returns on detailed knowledge of the physical world through digital data and technology, we needed a concrete example of physical placement, and we chose two the states in Republic of Armenia – Vayk and Sunik. These two neighboring states are defeated by radical digital changes. We have chosen Lidian Gold Armenia in the mining sector - complementary use of Lydian Gold Armenia's digital technologies. We have taken a number of technical and technological measures and made recommendations, which are set out below.

Formalized semantics and ontology turned out to be part of new tools for solving economic problems through innovations that ensure transparency. The mining and energy sectors, as well as the wider ecosystem of these states, have realized that innovation thrives on cooperation as well as competition. The exchange of knowledge is necessary for the development of new solutions, and it is possible only with their ontological formalization. The state is well provided with sectorial research institutes and programs; to achieve proper results, the research will require, as Armenia understands, cooperation

at the national and global levels. It is also necessary to collect formalized knowledge (Mkrttchian & Belyanina, 2018). The digital avatars, more precisely the expert knowledge generated by them, enable each member of the network, called a node, to contain a chain of blocks that makes up the history of transactions performed on the network.

Innovations in any industry depend on the ecosystem of suppliers, start-ups, research institutes, governments, service providers and asset owners. There is evidence that transformational new technologies are likely to evolve in complex, interdependent research ecosystems. The main problem of companies engaged in mining operations in states Vayk and Sunik is the lack of qualified personnel for very difficult working conditions. It is very difficult to find people who, even for a large salary (the average salary, for example, locomotive drivers there is about \$ 1,000 for a two-week watch) are willing to work in the constant stress and heat of states. Our research has shown that problems can be solved with the help of Mkrttchian's intelligent avatars (Mkrttchian & Aleshina, 2017). The proposed blockchain system can be successfully applied for Smart solutions in create Intellectual systems use Expert Knowledge. Such solutions gave such automation a processor, which led to a number of important achievements at the company's iron mines in the region. We began to use several automated heavy trucks, focused on shared GPS and video control technologies, so that this automation helped to ensure more efficient and safe movement of mining material.

We believe that there are conclusions that can be drawn at this stage: the research universities have a strong influence on local development; focusing on large-scale employers can crowd out small start-ups - we need much more information before an entrepreneurial policy can reach a relatively mature status, such as a policy on international trade and monopoly. The primary need is to experiment and evaluate, especially when randomizing. For example, if a government creates an entrepreneurial cluster that overflows, it can randomize at least some of the spaces in the cluster. Comparing the results of winners and losers in the "space lottery", the government can assess the impact of politics. If the government continues to provide loan guarantees on a sustainable basis, at least some of the loans can be randomly allocated in a way that allows for an assessment of the results of these loans. Today, experimentation is taking place throughout the Republic of Armenia, as the new government at all levels (along with numerous private and non-profit organizations) is developing a policy in the hope of creating its own national silicone bunker. The problem is that this experimentation has almost no future, and it is often unclear which outcome variables (i.e. the number of start-ups, employment, patents) are needed for this. Moreover, most policy-makers, especially when programs are relatively inexpensive, can naturally endorse such an approach, in which every potential intervention can contribute to the development of entrepreneurship, is considered simultaneously. In fact, efforts to provide entrepreneurial education, access to capital, promotion of exports, etc. are simultaneously not possible. In the region of the Republic of Armenia considered in this chapter, it is often beneficial for beginners to undertake what makes assessing any complex political interference difficult.

The described method is not developed enough and considered on small-sized real data only. Pilot testing gave the expected and correct result, but, obviously, before introducing the approach into real use, it needs to be developed and refined. Avatar interfaces (especially outputs) need to be adapted to real needs. The variety of data, on which the avatar is trained, should be significantly increased. The blockchain structure was not included in the implemented algorithm; accordingly, the blockchain model must be specified and implemented. And, naturally, at all stages of the subsequent development of the methodology, it should be tested on ever-increasing data size. When simultaneous analysis of several alternative (or related to different regions) business plans takes place, consideration of a population of avatars will be needed, and an environment of their interaction should be elaborated. The development of the technique is in progress, much work is needed to bring it to practical value.

FUTURE RESEARCH DIRECTIONS

Concerning practical applications, evaluation as a concept becomes more important for regional cluster initiatives, in particular, as well as other programs that contribute to the development of entrepreneurship. The key problem here is that plausible counterfeits against which benchmarks are measured are difficult to construct and therefore rarely considered, which makes interpretation of any results difficult. This is due to the fact that the use of randomization to create research opportunities is particularly complex in this area, where politicians often deliberately target specific areas for additional funding and where “winners and losers” are very visible.

CONCLUSION

Despite the fact that entrepreneurship is a powerful force that generates local and economic growth, it is not obvious that state policy can create entrepreneurship. Even if entrepreneurs are grouped in a small geographical unit, it is not obvious that the government should use state policy to support such clusters. While the above-mentioned business policy usually does not require large flows of funding, it is still important to consider the shortcomings of inefficient policies. At this point, we are still just beginning to acquire sufficient wisdom to create reliable policies that absorb the externalities that may come from innovations and new start-ups.

Thus, knowledge about microeconomic processes in the modern digital economy that lead to growth is still incomplete. In neoclassical growth models, the production of knowledge was exogenous - the technical remainder, whereas the dissemination of knowledge was either exogenous, stochastic or isolated to large firms that more closely resemble pharmaceutical companies in which research departments try to come up with the following combination of molecules that will turn into the next unit - booster.

But knowledge is developed, applied and disseminated in many other ways, often through smaller innovative firms and entrepreneurs. The uncertainty, asymmetry and high transaction costs inherent in knowledge also give rise to a divergence in the evaluation and evaluation of the expected value of new ideas. This discrepancy in the assessment of knowledge between economic agents and in the decision-making process of existing firms can induce agents to start new firms as a mechanism for assessing the (expected) value of their knowledge. This suggests that entrepreneurship facilitates the dissemination of knowledge in the form of creating a new firm.

To manage successfully the knowledge introduction one needs in powerful tools of “digital age”. The described methods can assist in improvement of the innovation process, in Armenia and, as well, in other part of the world.

KEY TERMS AND DEFINITIONS

Application of Blockchain Technology: Is application multifunctional and multilevel information technology designed to reliably record various assets in Digital Economy for help the technological challenges and created tools.

Avatar Model of High Technology: Is new model with natural intelligent for Avatar introduced in 2011 from Professor Vardan Mkrttchian.

Avatar-Based Management: Is new management technology in Digital Economy introduced in 2018 from Professor Vardan Mkrttchian.

Blockchain Technology: Is a multifunctional and multilevel information technology, designed to reliably record various assets in digital economy.

Entrepreneurs to Real Using Emerging Tools: Is entrepreneurs for the real use of new tools is a new approach to the concept of entrepreneurial phenomenon in a regional digital economy that can be used both at the national and national levels introduced in 2018 from Professor Vardan Mkrttchian.

Help and Control System: Is the system of reference and control is a new system based on knowledge and used for entrepreneurial in a digital economy introduced in 2018 from Professor Vardan Mkrttchian.

Sharing Digital Resource: Is exchanged of the digital resource is a new type of cooperation between enterprises in the digital economy in the form of knowledge obtained from digital avatars introduced in 2018 from Professor Vardan Mkrttchian.

Understanding SME Techno–Entrepreneurship in Nigeria’s IT Clusters

Immanuel Ovemeso Umukoro

Lagos Business School, Pan-Atlantic University, Nigeria

INTRODUCTION

The adoption of technology in everyday business and social life has created thousands of jobs in the form of micro, small, and medium enterprises (MSMEs) which have become significant contributors to gross domestic products (GDP) of several national economies. These MSMEs overtime aggregate to form business clusters that are typical of innovation hubs, technology clusters, and commercial nerves that support business and everyday lifestyle. These clusters have become integral to the development of local contents for solving indigenous problems. Waldman-Brown, Obeng and Adu-Gyamfi (2013) define a cluster as a large conglomeration of firms in related industries, located in a specific region. Entrepreneurs in information and technology clusters largely depend on informal knowledge in order to acquire skills that will enable them effectively tackle IT problems. Bakar and Zainol (2015) note that these entrepreneurs (especially those in technological clusters) have the potential to advance indigenous technology if well nurtured. Their reliance on informal knowledge continues to grow mainly because they are mostly artisans who have no formal education. Given the need to grow their competence and innovativeness, networking and collaboration among co-operators within and outside ICT clusters where they operate are have become imperative.

There is also the rapid-obsolescence of technology which means that new knowledge of emerging technologies is needed to meet service support needs. Entrepreneurs must be able to identify and absorb knowledge from the immediate and wider environments in order to meet their clients’ needs. This requires interaction with different types of actors for the accumulation, synthesis and codification of the relevant information and knowledge needed to actualize different types of innovations (Nwagwu & Ibeku, 2016; Tepic *et al.*, 2012). Innovations occur in various establishments; however, innovative technology businesses are often located in clusters (Baptista & Swann, 1998; Porter, 1998; West, 2001; David-West, Umukoro, & Onuoha, 2018) in what is typical to business incubation and acceleration setting. Similarly, collaboration or teamwork also facilitates the development of new ideas that might emanate from customers, employees and competitors. For example, feedbacks from customers on a product’s use could be considered useful in the subsequent modification or design of the product. Through this iterative knowledge reconstruction, new products (frugal outcomes) that are tailored towards customer needs begin to evolve through a frugal mindset and process (David-West, Iheanachor & Umukoro, 2019a).

Nigeria has over the years been a large consumer of information and communication technologies with low innovative and development capabilities in the IT space. The cost of technology is however often too high for the mass market, thus calling for a frugal mindset in bridging the technology divide between and within nations (Soni & Krishnan, 2014) classified as developed, developing and under-developed economies. There is also the digitisation of businesses and processes alongside the emergence of new business models that disrupt the incumbent traditional pipe businesses (David-West *et al.*, 2018).

DOI: 10.4018/978-1-7998-3473-1.ch102

In response to this digital disruption, many businesses have now migrated from the traditional model for digital enterprises while some are still in their evolutionary stages. This paradigm shift has created another category of entrepreneurship known as techno-entrepreneurship that is manned by a new archetype of entrepreneurs now framed as techno-entrepreneurs or digital-entrepreneurs.

Ironically, the concept of what attributes characterise techno-entrepreneurs, how they behave, and their levels of engagements across different levels of assets, resources and capabilities (ARCs) within IT clusters is yet to be documented. This is necessary as it helps in designing capability measures that help develop the ecosystem as well as strengthen local content for meeting national information and communications for development (ICT4D) priorities. This study therefore critically examines the emergence of techno-entrepreneurship in Nigeria's IT clusters and its role in the development of information technology products and services in solving first, Nigeria's local IT demands, and Africa at large. The rest of the chapter is organized as follows. Following this introduction, a brief description of the methodology adopted is provided, and after that, an overview of the concept of techno-entrepreneurs and SME techno-entrepreneurship is provided. This is followed by a section on SME techno-entrepreneurship clusters in Nigeria; attributes of SME techno-entrepreneurship in Nigeria, its relevance to the ICT ecosystem growth as well as national development. The paper concludes with a section on challenges and opportunities of SME techno-entrepreneurship in Nigeria.

BACKGROUND

This chapter is a conceptual framing of the concepts and issues of SME techno-entrepreneurship in Nigeria's ICT clusters. While the findings reported are not empirical, they are evidence of a rigorous literature review and ecosystem observation of the SME techno-entrepreneurship ecosystem in Nigeria. Three established ICT clusters that have been major contributors to Nigeria's economy were purposively selected and observed in this study. In order to provide a conceptual framing of techno-entrepreneurship practices across ICT clusters, a review of related literature was carried out. This was used to arrive at substantive concepts and issues which were later validated through cluster observations. A literature search using internet keyword searches was performed using dedicated databases such as JSTOR, Google Scholar, Emerald Insights, Ebscohost and industry publications between November 2018 and October 2019. Using an integrative approach to objectively critique, summarize and draw conclusions (Christmals & Gross, 2017; LoBiondo-Wood & Haber, 2010), themes on techno-entrepreneurs, SME techno-entrepreneurship, SME techno-entrepreneurship clusters in Nigeria, attributes of SME techno-entrepreneurship in Nigeria, and relevance of SME techno-entrepreneurship to ICT ecosystem growth as well as national development were explored. Relevant and related themes were further clustered, analysed and synthesise for coherence using a 'Best Fit' approach (Carroll *et al.*, 2013) involving a two-phase analysis. The first phase was to cluster similar themes and synthesis of same for coherence to arrive at an academic viewpoint, while the second phase involved synchronization of the output of the first phase to arrive at the conceptual framing presented in this chapter.

Overview of Techno-Entrepreneurs and Techno-Entrepreneurship in Nigeria

Techno-entrepreneurs devise and harness new strategies of solving IT problems in a frugal manner amidst resource constraints relating to assets, resources, and capabilities. These concepts have been studied in-depth in innovation literature (Ibeku, 2018; Nwagwu & Ibeku, 2016; Tepic *et al.*, 2012; Klerkx and

Leeuwis, 2009; Nooteboom *et al.*, 2007; Reagans & McEvily, 2003 and Hansen, 1999). Specifically, techno-entrepreneurship is broadly defined as the process of creating new technological and internet-driven businesses, products, and services with the ultimate goal of driving efficiency and achieving a high return on investment (David-West, Omotayo & Umukoro, 2019b). It is the manner through which entrepreneurs draw on resources and structures to exploit emerging technology opportunities (Liu *et al.*, 2005). Van Welsum (2016) argues that techno-entrepreneurship encompasses both digital startups and existing businesses that incorporate information and communications technology (ICT) towards enhancing existing business processes and activities.

In conceptualising techno-entrepreneurship, Bailetti (2012) identifies four definitive elements. These are: the ultimate outcomes (including value creation and value capture); target of the ultimate outcome (the firms for which value is created and captured); delivery mechanism (the methods and approaches used for delivering the value created and captured); and interdependence of the delivery mechanism with scientific and technological advances that enterprises must harness to co-produce an intended output. Consequently, David-West *et al.* (2019b) posit that techno-entrepreneurship is designed to create and capture value for an enterprise by systematically aggregating assets, resources and capabilities via the intermediation of technology. The importance of techno-entrepreneurship lies in its ability to identify problems as well as apply technology to create the desired solution. Its significance also lies in the ability of techno-entrepreneurs to search for technological innovations that are capable of generating new solutions, launching new ventures, and exploiting new market opportunities. Techno-entrepreneurship can create and deliver customer value propositions more efficiently and effectively through the development of a frugal mindset by techno-entrepreneurs.

SME Techno-Entrepreneurship Clusters in Nigeria

The Otigba Computer Hardware Cluster, Lagos: The cluster otherwise known as the Ikeja Computer Village in Lagos, Nigeria evolved from trading in imported IT components and products in the early 1990s. Between 2002 and 2003, the cluster had grown to consist of 2,500 sales and repair outlets and has become a beehive of IT activities. The cluster consists of trained and untrained experts and artisans who engage in trading, supply, and repairs of IT facilities ranging from computers, telecommunication equipment, satellite technologies and services, and mobile phones. This network of suppliers, buyers, repairers, clone builders, and components traders at Otigba cluster has generated an intensely competitive environment and a local milieu that provide for a significant knowledge base for the future of Nigeria's IT revolution (Nwagwu & Ibeku, 2016; Oyelaran-Oyeyinka, 2014).

The Abuja ICT Clusters: Abuja is Nigeria's seat of government, and with heavy political presence, the city enjoys the government's most exceptional policies and initiatives. This is also true in the area of techno-entrepreneurship clustering as the federal capacity territory houses a handful of ICT clusters. There is the Abuja Technology Village (ATV) which is home to the Science and Technology Park (STP) as well as Special Economic Zone (SEZ). The ATV has the objective of becoming Africa's destination of choice for technology research, incubation, development and commercialisation in four strategic sectors vis-a-vis information and communication technology, biotechnology, minerals technology and energy technology. Operated by the federal government, there is also a proposed launch of the 'ICT Parks' that will house different clusters of technology companies in the FCT and those near universities to help nurture fledgeling technology industries by developing pools of natural, naive and evolving talent. The proposed ICT Park has an extended objective of driving the growth of existing technology-based

companies. It will also facilitate the growth of SMEs, develop digital capacity and entrepreneurial skills aimed at promoting a digital economy as well as attract significant national and international companies, thereby attracting inward investments, create world-class physical facilities and proactive support services.

Abuja also plays host to a GSM and Computer Village – a bustling market that caters for techno-entrepreneurial services such as sales, maintenance, and repairs of phones, computers alongside artisanal service offerings. The Abuja GSM Village as it is fondly called boasts of a diverse SME techno-entrepreneurs including laptop engineers, software engineers, mobile phone technicians, technology hardware vendors, and other non-techno-entrepreneurs who provide support services. Like other ICT clusters, this cluster boasts of young entrepreneurs – both university graduates and non-graduates who have gone through internship and artisanship. A tour of the Abuja GSM and Computer Village justifies its signature of being the melting pot for electronic devices in the nation's Federal Capital Territory. The high sense of ingenuity and creativity of techno-entrepreneurs exhibited through their reverse engineering, repairs, cloning, and installation activities make one question the intellectual capacity of device manufacturers.

The Yaba ICT Cluster, Lagos: Yaba has been one of Africa's rising technology hubs over the last two decades and remains the hardest evidence of an emerging technology ecosystem in Nigeria. Although the popular Otigba (Computer) Village remains the biggest ICT cluster in Nigeria, it is most known for its focus on hardware. On the contrary, the Yaba ICT cluster or Yabacon Valley as it is fondly called is a software hub that houses Nigeria's software powerhouses such as Co-creation Hub (CcHub), Andela, NG-Hub (powered by Facebook), BudgIT, Blue Lab (powered by Stanbic IBTC), Digital Lab (powered by FirstBank), PagaTech, and others that serve as incubators and accelerators to many digital star-ups. Until more recently, the ICT cluster has largely operated without much of coordination before key players came together to carve the Yaba ICT Manifesto – a framework for the Yaba ICT Cluster. The Yaba ICT cluster is conceived around seven key objectives of culture, funding infrastructure, talent and skills, policy, Yaba as a testbed for a smart city, and research & development. The cluster has been developing organically for about a decade or more with pioneer organisations such as the Co-Creation Hub (CcHub). The community is now working on an initiative that will further develop the Yaba ICT cluster as a hub for knowledge, innovation, technology and entrepreneurship. This is with the aim of creating an enabling environment which facilitates and supports the development of a technology and innovation ecosystem for Nigeria, and the rest of Africa. The Yaba ICTcluster also enjoys government participation through the Ministry of Science and Technology, the Ministry of Wealth Creation and Employment, and the Ministry of Physical Planning & Urban Development¹. The likes of Google, Microsoft, MainOne, Andela, General Electric (GE), CcHub, Flutterwave, University of Lagos, Lagos State University and Ibile Broadband make up the industry advisory board (IAB). The focus of the IAB is to improve an enabling environment that promotes infrastructure, policy regulation and governance, access to funding, access to market and demand, research & development, talent, skills & education, networks & collaboration, advocacy and marketing, and strategic partnerships.

Types of Techno-SMEs in Nigeria's ICT Clusters

Techno-entrepreneurship began with the adoption of information and communications technologies (ICTs) as time-saving and cost-reduction tools with which small business owners met their communication rather than information-processing needs (Ducomber & Heeks, 2002). The growing mobile penetration rate and its impact on today's digital economy continue to drive the adoption and application of ICTs in

many business endeavours. Micro, small and medium scale enterprises (MSMEs) also continue to exploit the business opportunities that have opened up consequent of the digital economy. The digital economy is underpinned by the power of the interconnectedness of mobile and other digital technologies with which economic activities are carried out with the ultimate goal of developing innovations from ideation, design, testing and prototyping, and the commercialisation of such innovations. In a study conducted by Nwagu & Ibeku (2016) on technology products and services operators in the Otigba Computer Village, the authors report that key activities that are undertaken in the cluster include but not limited to sales, repairs, cloning, installation, and maintenance of technology artefacts.

Techno-entrepreneurship in Nigeria's ICT clusters can be broadly classified into two archetypes. These are formalised techno-entrepreneurship and non-formalised techno-entrepreneurship. Using the typology developed by Waldman-Brown (2018) in categorising SMEs in manufacturing clusters, the two archetypes can be further described as follows:

- i. **Formalised Techno-SMEs or Techno-Entrepreneurs:** These are SMEs that have formalised business structures and registered with the Corporate Affairs Commission (CAC). They are usually into wholesale and retail of ICT hardware and software services, as well as large-scale ICT service provisionings such as repairs, maintenance, installation, and other professional IT services. They can be specialised (focusing on a particular line of IT service offering) or blended (providing a variety of ICT services that cut across different businesses). This archetype of entrepreneurs enjoys a *virtual factory* of networking with both internal and external stakeholders to be more productive. While their level of formalisation can be a driver of entrepreneurial success, Waldman-Brown (2018) argues that the virtual network of infrastructure that they enjoy is the key to entrepreneurial progress.
- ii. **Non-Formalised Techno-SMEs or Techno-Entrepreneurs:** These are SMEs with very few employees with widely-variable office space or 'workshop' dedicated to their entrepreneurial activities. They are likened to what Waldman-Brown (2018) describe as *craft SMEs*. These techno-entrepreneurs typically employ low-tech equipment and significant manual labour and are, in most cases, not formally-registered businesses. Majority of their workforce is made up of artisans who are eager to learn an ICT-related skill and would even pay apprenticeship fee. In line with what is seen in Nigeria's techno-entrepreneurship clusters, The International Labour Organisation (2016) describes this type of non-formalised entrepreneurship as one that comprises almost exclusively of informal enterprises and remains the second-largest source of jobs in emerging markets after agriculture. Waldman-Brown (2018) further notes that rather than employing automation or industrial-scale equipment, these entrepreneurs tend to lack a clear division of labour. They typically operate a *job shop style* where workers use whatever materials and equipment available to them rather than the *flow shop style* where tasks and workflows are scheduled in advance. This is because these striving entrepreneurs are constrained with the needed resources that are needed to become well established. Nwagwu and Ibeku (2016), however, note that the ability of these entrepreneurs to draw on their informal networks is a driver of their innovativeness.

Table 1 shows the different types of service offerings provisioned across these two archetypes of techno-entrepreneurship.

Table 1. Services offered by SME Techno-entrepreneurship Types

Formalised Techno-entrepreneurship	Non-formalised Techno-entrepreneurship
Sales & marketing – wholesale and retail	Sales (retail of mostly used parts and low-price accessories)
Maintenance of hardware and software (corporate clients)	Maintenance
Product development (software)	Cloning & refurbishment (mostly mobile phones, computers, accessories)
Repairs (service centres for OEMs)	Repairs (often powered by reverse engineering)
Installation (computer networks, internet, protocols, etc.)	Installation (applications, parts, etc.)
Incubation, acceleration & internship	Apprenticeship

Frugal Innovation and SME Techno-Entrepreneurship Nigeria

Various forms of exclusion including financial exclusion (lack of access to formal financial services), social exclusion, economic exclusion, as well as digital exclusion exist at the bottom of the pyramid (BOP) segment. This is because members of the BOP are characterised by low-income, low literacy levels, rurality, low digital self-efficacy, and such others. One of the critical advantages of techno-entrepreneurship is its role in creating technological solutions amidst resource constraints. David-West *et al.* (2019a) report that to be frugal amidst resource constraints, an innovation must address all dimensions and processes relating to the conceptualisation and production of products and services. Accordingly, Sammut-Bonnici and McGee (2015) describe the term frugal innovation as the practice of simplifying product components and manufacturing processes into basic elements, to redesign both the product and the processes to become more efficient and cost-effective. Frugal innovations are those innovative products and services specifically designed with a frugal mindset and processes to achieve a frugal outcome that promotes inclusiveness at the BOP in terms of affordability, accessibility, and usability.

Techno-entrepreneurship seeks to evolve products and services that are cost-effective and less complex in terms of usability, especially for a market segment that would have been excluded either by cost or design sophistication. Nigeria's ICT clusters are characterised by elements of frugal innovation and can, therefore, be described as frugal innovation hubs. This is because many of these techno-entrepreneurs exhibit a frugal mindset and processes that translate into frugal outcomes (low-cost and less complicated products and services) that address the economic needs of the BOP segment. The frugality of a product or service stems from three key underlying assumptions that a) it has to be conceived by a frugal mindset, b) it is driven by a frugal process, and c) the outcome must be frugal in nature. Frugal innovations, therefore, involve a combination of frugal mindset, a frugal process, and a frugal outcome.

Attributes of SME Techno-Entrepreneurship in Nigeria

Frugal Mindset

A frugal mindset depicts how a producer prudently manages meager resources to meet the development of quality products and services targeted at low-income customers. The inability of businesses to exhibit a frugal mindset towards meeting the needs of the BOP customer segment can lead to expensive products and services that are unfit for the intended market segment (David-West *et al.*, 2019a; Weyrauch & Herstatt, 2017; Lehner & Gausemeier, 2016). Techno-entrepreneurs across Nigeria's ICT clusters evolve or innovate solutions that meet the needs of the BOP through a frugal mindset. This is because, given

the resource constraints faced by these entrepreneurs, they embark on component re-use by sourcing for usable parts of non-working technological artefacts by dismantling and assembling them to evolve whole new products. Another dimension of a frugal mindset is to strip products or services of unnecessary costs and features – a process also known as value innovation. While the former is most practised in a resource constrained environment and most seen in Nigeria's frugal innovation hubs and ICT clusters, the latter is most embarked on by formalised, established and large-scale SMEs.

Using Radjou *et al.* (2013) six principles of frugal innovation, it can be argued that a frugal mindset must (i) find opportunities in adversity and transform constraints into opportunities; (ii) must do more with less; (iii) the innovation must think and act with agility; (iv) it must aim for simplicity; (v) must involve the marginal population; and (vi) follow the innovator's heart. A frugal mindset is also exhibited by Nigerian techno-entrepreneurs resource discovery ability. Most of these entrepreneurs operating out of these ICT clusters see '*things*' as resources where others do not imagine them as resources. By stretching and applying such resources in new ways, techno-entrepreneurs can utilise these resources without paying or paying much less than they are worth (Sharmelly & Ray, 2018; Ng, Grafton, Tan, & Tan, 2018). In other words, these techno-entrepreneurs exhibit a frugal mindset which Korsgaard *et al.* (2018) referred to as *spatial bricolage*².

Frugal Processes

A frugal process entails the creation of value for the end-customer with minimal wasteful efforts that would otherwise have translated into high cost-to-use. David-West *et al.* (2019a) posit that frugal innovation takes low-cost strategies that succeed by leveraging lower cost structures through economies of scale to appeal to mass markets. They further note that while the low price of frugal product or service can result in proportionately small margin per product, profitability is achieved through economies of scale that is reached at the mass-market segment. In several ICT clusters in Nigeria, especially the hardware clusters, what most techno-entrepreneurs embark on is a lean approach to product innovation, development, and service delivery. Sammut-Bonnici and McGee (2015) describe this type of frugal process approach towards innovation as constraint-based and reverse innovation. The Economist (2010) notes that beyond product redesign, a frugal process re-imagines the entire production processes and business models to be more customer-centric in terms of affordability and usability.

Frugal Outcomes

A frugal outcome is essentially an end product or service that addresses the underserved or excluded markets at the low-end of an economic system; or products and services that primarily meet the needs of developing markets. David-West *et al.* (2019a) posit that the BOP customer segment is disconnected from the formal economy due to lack of critical development infrastructure that is needed to drive businesses and commercial activities. Such challenges that constrain businesses from serving the BOP segments profitably and sustainably have also created opportunities for frugal innovations (David-West *et al.*, 2019a). Addressing this market segment calls for entrepreneurs to develop frugal outcomes (Tiwari, Fischer & Kalogerakis, 2017a&b; Tiwari, Fischer & Herstatt, 2016 Nunes & Breene, 2011; Zeschky, Widenmayer & Gassman, 2011).

How do techno-entrepreneurs operating out of Nigeria ICT cluster achieve frugal outcomes? Products and services sold and offered across these ICT clusters are people-centred, small-scale, less labour-intensive, energy-efficient, environmentally sound, and locally controlled. Soni and Krishnan (2014)

classified these features as *appropriateness of technology*. Also, products and services provided by these techno-entrepreneurs address the needs of under-served or unserved markets at the low-end of the economic system. Soni and Krishnan (2014) classified these features *bottom of the pyramid innovation*.

Networking

According to Aalst (2003), networking relates to the systematic establishment and use of internal and external links between people, teams or organisations to improve performance. Networking is an essential entrepreneurial culture in a social system. Interaction and communication with people could bring advantages such as business opportunities, improved skills and expansion of customer base among others. Business organizations, therefore, require networking with one another to grow (Nwagwu & Ibeku, 2016). Through relationships with other organisations in the same business area or other complementary areas, there is a possibility for the development of new techniques, processes, and products. Innovators in clusters collaborate to be able to attain competitiveness because participating units and individuals complement one another to retain competitive advantage and to ensure continued relevance in the sector. Also, collaboration with actors that are external to the business clusters such as knowledge-intensive institutes, universities and technology developers, among others, can contribute to new product and service delivery concepts. For techno-entrepreneurs, maintaining an active network is needed to develop a critical entrepreneurial relationship. Garnsey (1998) opines that in the initial phase of a business, entrepreneurs should be able to access, mobilise, use resources existing in the environment for gaining benefits.

These interactions among members of technology clusters are essential for the acquisition of diverse forms of new knowledge, leading to innovation and innovativeness (Tepic *et al.*, 2012; Nooteboom *et al.*, 2007; Reagans & McEvily, 2003; and Hansen, 1999). Furthermore, techno-entrepreneurs require networking as an essential means to develop relationships that could help them grow in their businesses (David-West *et al.*, 2019a; Hagedoorn & Schakenraad, 1992). Although the idea of networking is as old as history and transcends academic fields and disciplines, information technology objectifies and has expanded the meaning and application of networking because it creates opportunities for people to interact in real-time from their dispersed locations. In light of this, Garcia-Morales, Martín-Rojas and Lardón-López (2018) note that leveraging network effects and knowledge flows through the use of emergent phenomena can help firms create business value that meet customer growing needs. They also submitted that by changing the way different agents and organizations communicate, valuable connections that transform business models can be established. Techno-entrepreneurs must, therefore, engage in networking activities to acquire new skills for improved service delivery and innovation. This attribute is manifested in Nigeria's information technology clusters (Nwagwu & Ibeku, 2016).

Networking in Clusters for Innovativeness

The geographical clustering of inter-networking firms continues to gain significance in the business community and attracted intense research attention (Ibeku, 2018; Ibeku & Nwagwu, 2016; Porter, 1998). It is frequent to encounter innovation networks and hubs around ICT clusters as they share non-transactional elements – an environment that is traditionally used to sharing information and knowledge indispensable for innovation (Jorge, Maria & Irina, 2004). It is widely accepted that cluster consolidation and development is intimately related to ties and linkages with other firms and institutions and is highly dependent on behavioural imitation. The importance of networking to innovativeness cannot be understated. It is in light of this that Huang and Wang (2018) stated that that weak network ties facilitate

exploratory learning, whereas strong relationships influence exploitative learning. Thus, individuals need to have the ability to interact and cooperate with other actors to reduce uncertainty and foster relevant complementary knowledge (Jorge *et al.*, 2004). Such interactions and cooperation should cut across actors within and outside clusters.

Using the description of weak and strong network ties earlier provided by Huang and Wang (2018), Nigeria's techno-entrepreneurs operating out of ICT clusters enjoy a mix of weak and strong network ties. Weak network ties exist where there is a conspicuous absence of formalised institutions (such as government ministries and agencies that are concerned with information technology and education) and businesses such as original equipment manufacturers and software companies. Strong network ties, therefore, exists where there is direct and obvious participation of formalised institutions and businesses that help catalyse the development of the needed assets, resources and capabilities required by techno-entrepreneurs to be frugally innovative yet profitable and sustainable without compromise on quality.

In specific clusters like the Yaba ICT cluster, there is a visible presence of technology firms that provide incubation and acceleration support to techno-entrepreneurs. Networking ties within such cluster is very high and does drive high innovativeness among techno-entrepreneurs. In places clusters like Otigba (computer) village, there is a mix of strong and weak networking ties. While there is a strong presence of known technology brands such as Samsung, Apple, Hewlett Packard, Dell, Techno, Infinix Mobile, and more, what is mostly witnessed is wholesale dealership with some level of technical training for local entrepreneurs that help provide after-sales support services in terms of repairs and

Figure 1. Techno-entrepreneurs' Network Ecosystem

installation. Weak networking ties becomes apparent when there is no transfer of knowledge on how to frugally innovate IT products and services for solving indigenous problems faced by the bottom of the pyramid market segment. Where there is a marked absence of strong networking ties, what most Nigerian techno-entrepreneurs result to is horizontal networking where there is a transfer of knowledge between entrepreneurs within the cluster. Oyelaran-Oyeyinka (2006) describes this kind of horizontal networking tie as inter-personal learning and collaboration between its techno-entrepreneurs. Figure 1 shows the nature of SME techno-entrepreneurial networking in Nigeria's ICT clusters.

Innovative Behaviour

The ability to introduce an innovation is one of the most important aspects of a social system's process (Nwagwu & Ibeku, 2016). Consequently, the need for techno-entrepreneurs in an IT cluster to have the capacity to develop novel ways of addressing old and new IT problems using new and existing strategies remains pertinent. This is important especially in an economy whose ICT sector relies heavily on importation to meet her IT infrastructural demands amidst the challenges of local content development. Literature evidence suggests that although, techno-entrepreneurship is still at its nascent stages of development (David-West, Muritala & Umukoro, 2019), Nigeria's techno-entrepreneurs operating within IT clusters have demonstrated various levels of innovative capabilities in order to serve their customer segments efficiently with quality home-grown solutions. Although a certain level of innovativeness characterises techno-entrepreneurship in Nigeria's ICT clusters, there is the question of whether these techno-entrepreneurs have sufficient capacity to innovate quality IT products and services.

Ibeku and Nwagwu (2016) report that there is a strong relationship between the ability to innovate within a cluster and the networking behaviour that takes place. Similarly, Oyelaran-Oyeyinka (2014, 2006) reports that the strength of clusters lies in the quantity and quality of networking ties that exist between members. He referred to networking links as the inter-personal learning and collaboration among members of the cluster. It is pertinent to note that although Nigerian ICT clusters have not recorded strong networking ties, they have continuously driven their innovative practices by leveraging horizontal networking.

Understanding the Nature of SME Techno-Entrepreneurship Clusters in Nigeria

As earlier noted, techno-entrepreneurship in Nigeria is dominated by two distinct categories of entrepreneurs – formalised small and medium enterprises and non-formalised small and medium enterprises. The nature of SME techno-entrepreneurship can be described using the dominant attributes exhibited by techno-entrepreneurs as well as the types of activities undertaken by these entrepreneurs. The national system of innovation can be used to map the nature of SME techno-entrepreneurship in Nigeria's ICT clusters. Though nascent, David-West *et al.* (2019a) posit that frugal innovation theory negates assumptions that innovation occurs because of the existence of slack resources and supporting institutions, thus contrasting Lundvall's (1992) theory which argues that innovation occurs only in the presence of the correct components of the National System of Innovation.

In consonance, Bhatti (2012) posits that frugal innovation does not occur in the presence of organisational slack and institutional mechanisms but occurs when there is a social need, resource constraints, and intuitional voids. Techno-entrepreneurship does occur where there is a need to meet or a market void to fill. In consonance, Dodgson (2018) and Awoleye (2013) also posit that innovation is achieved

by meeting challenges in a manner in which better, more efficient, and skillful approaches are employed in the business processes. Given, SME techno-entrepreneurs exist in a cluster where both formal and informal linkages and networks can be leveraged to overcome resource constraints. As social needs arise, alongside the quest to meet such needs amidst resource constraints and institutional voids, techno-entrepreneurs develop a frugal mindset to prudently utilise meagre resources using frugal processes for the development of frugal outcomes (quality products and services) targeted at low-income customers. To address resource constraints, techno-entrepreneurs operating within ICT clusters engage in networking activities within and outside the clusters. Through this process, entrepreneurs' innovative abilities are enhanced. Similarly, Dodgson (2018) reports that networking is important as it can lead to increased scale and activities which in turn translate into wider customer base. In Figure 2, the chapter proposes

Figure 2. Proposed Model of SME Techno-entrepreneurial Practice in ICT Clusters

a model that describes the nature and flow of techno-entrepreneurial practice in Nigeria's ICT clusters.

The Relevance of SME Techno-Entrepreneurship to Nigeria's ICT Ecosystem

Techno-entrepreneurs remain critical to the development of Nigeria's ICT ecosystem as the bridges between those that are digitally included and those that are not through their frugally innovated homegrown solutions. One of the problems faced by emerging economies is the development of local ICT capacity for solving everyday problems. In light of this, Waldman-Brown (2018) submits that innovation-driven entrepreneurs have the potential of playing a significant role in supporting development, be it in the formal or informal sector. Their ability to support small-scale experimentation with novel techniques for solving ICT problems is significant to ecosystem development.

Through ecosystem partnership, networking which is a key attribute of techno-entrepreneurship can help attract industry players that will invest in ICT clusters in developing the capacity needs of local techno-entrepreneurs for an enhanced innovative culture. Such networking interactions have the capability of producing spin-off firms from research projects, as well as birthing new digital start-ups following successful incubation and acceleration programmes. Also, investment in techno-entrepreneurship can and has generated foreign direct investment (FDI) for Nigeria's ICT sector as has been witnessed by the likes of Farmcrowdy, Flutterwave, Paystack, Piggyvest, Andela, CcHub, and the likes.

Nigeria's techno-entrepreneurship, especially across ICT clusters, has contributed to the development of human capacity in the ICT sector. Many of these techno-entrepreneurs continue to remain internship centres that absorb fresh graduates and students undergoing the *student industrial work experience (SIWES)* programme that is mandatory for most programmes offered across Nigerian universities. These young individuals are provided with an environment where they get hands-on experience using a test-and-learn approach. On the other hand, it allows techno-entrepreneurs to subsidise labour cost by absorbing these inexperienced graduates and undergraduates who are in needs of practical skills. In essence, techno-entrepreneurship in Nigeria's ICT clusters can help bridge the functional skill gaps existing between the academia and industry.

Challenges and Opportunities of SME Techno-Entrepreneurship in Nigeria

While there continues to remain a debate on the quality of home-grown solutions, questions relating to what role networking behaviour plays amongst members within and outside ICT clusters, and if the members of a cluster have sufficient skills to innovate, remain unanswered. These skepticisms require immediate attention in order to drive and enhance collaboration and innovativeness in Nigeria's IT sector which is also considered as one major way to developing local contents. Although there are noticeable levels of networking, innovativeness and some elements of frugality among the techno-entrepreneurs found in Nigeria's ICT clusters, formalised techno-SMEs are more positioned to exploiting the opportunities that abound in the techno-entrepreneurship space. While the non-formalised techno-SMEs exhibit some level of the attributes identified earlier, they do need government and industry support for driving their entrepreneurial effectiveness.

In terms of opportunities that exist in SME techno-entrepreneurship, David-West et al. (2019b) identified mobile technology, broadband, the sharing economy, and digital platforms as four key areas of opportunities that will drive SME techno-entrepreneurship not just in Nigeria, but across Sub-Saharan Africa (SSA). Mobile phone ownership continues to surge across Africa and has the potential of creating opportunities in the areas of sales, repairs, maintenance, and even manufacturing as is currently witnessed in Rwanda. David-West et al. (2019a) note that the opportunities brought by mobile penetration are evident in how mobiles are being deployed in ways that have not been tested before, even in some advanced economies. The employment and income-generating opportunities remain massive and will continue to grow as smartphone adoption continues to rise. In the area of broadband, entrepreneurs that operate technology-based ventures will significantly benefit from high penetration and ease of access through the *horse speed* internet across the region which in no doubt will support innovations (De Beer et al., 2017).

Technology makes sharing possible, and with the emergent sharing economy, many entrepreneurs have begun evolving their business models to launch new technology start-ups. For resource-constrained entrepreneurs, the opportunity to share co-working spaces, hardware and software has now been made possible. This is because technology makes sharing and consumption cheaper. This is very prominent in the Yaba ICT clusters where the likes of Co-creation Hub (CcHub) are using the business incubation and acceleration models to develop techno-entrepreneurs for Nigeria and Africa at large. David-West et al. (2018) report about 675 digital platforms across sub-Saharan Africa with Nigeria having the highest (194) platform concentration. The opportunity provided by platforms is seen across Africa with other countries such as South Africa boasting having about 108, Kenya with a total of 78 platforms, Ghana with 37, while Cameroon and Tanzania have 24 platforms each (David-West et al., 2018). There are also opportunities for SME techno-entrepreneurship in the area of incubators, hubs, and accelerators.

David-West *et al.* (2019b) note that though technology hubs in Africa are still at their nascent stages, they are growing by leaps and bounds and have received sizeable amount of investment from venture capitalists and angel investors within and outside the region. Technology hubs, alongside incubators and accelerators have a potential of providing the needed support for new digital start-ups.

CONCLUSION AND RECOMMENDATION

This chapter shows the nature of SME techno-entrepreneurship across Nigeria's ICT clusters by defining the attributes that characterise techno-entrepreneurs in information and communication technology clusters. The chapter conceptualises that SME techno-entrepreneurship lies at the intersection of a frugal mindset, frugal processes, networking and innovative behavior, all of which lead to the development of frugal outcomes that meet the needs of the mass market. There is a need for networking among techno-entrepreneurs through formal and informal linkages with one another as well as institutions such as universities, polytechnics and research institutes, and industry practitioners. This can foster the development of needed assets, resources, and capabilities (ARCs) that drive techno-entrepreneurial innovativeness. When compared to the findings of Abiola (2006) on the level of networking amongst technology artisans in Nigeria's IT clusters, this chapter shows that while the level of collaboration among techno-entrepreneurs is largely informal, promoting diversity of means (vertical and horizontal linkages) through which knowledge is acquired is important for the development of frugal outcomes, and for the growth of cluster techno-entrepreneurship.

The chapter recommends the establishment of government's ministries and agencies such as the Federal Ministries of Communications Technology, Science and Technology, Commerce and Industries, and Education, the Nigeria Information Technology Development Agency (NITDA), National Office for Technology Acquisition and Promotion (NOTAP) and other stakeholders in the public and private sector that are concerned with information technology and education. This will enhance the innovative behavior of techno-entrepreneurs as well as technology start-ups in Nigeria's ICT clusters. Government must, therefore, encourage networking and knowledge transfer through establishment of knowledge hubs that will aid techno-entrepreneurs' innovativeness at enhancing local content development as well as facilitate economic growth. Furthermore, government needs to initiate and monitor the right policies that will encourage private sector participation in terms of partnerships in the areas of establishment of investment vehicles, entrepreneurial development through skills acquisition, and regulations towards enhancing global best practices.

Future Research Directions

Very few studies exist on SME techno-entrepreneurship and where such exist, the focus has been on formalized SMEs. Despite the importance and contribution of cluster techno-entrepreneurship towards solving local problems, less attention has been paid to understanding the nature of these techno-entrepreneurs operating out of ICT clusters. While this chapter has provided a conceptual framing for understanding SME techno-entrepreneurship across ICT clusters, the concepts and issues presented in this chapter need to be empirically validated as the chapter only presents evidence from literature and cluster observations. Also, the model proposed in this chapter needs to be tested and where necessary, improved upon.

KEY TERMS AND DEFINITIONS

ICT Cluster: This is an aggregation of formalized and non-formalized businesses within a location with specialized business functions or activities focusing on a particular industry or sector.

Information and Communication Technology: This is a term used for describing all technologies that facilitate the processing, access to, storage, manipulation, use and exchange of information between a sender and receiver of information across various media.

Information and Communications Technology for Development (ICT4D): This refers to the use of technology for helping poor and marginalised individuals and communities in developing countries to bridge the digital divide and aiding economic development by ensuring equitable access to up-to-date communications technologies.

Innovative Behaviour: This refers to an entrepreneur's tendencies and practices aimed at devising new solutions or development of new products and services for solving identified problems.

Networking: This is a formal or informal interaction that is established by entrepreneurs with co-entrepreneurs or with suppliers, government, as well as other institutions and agencies within and outside a business cluster or ecosystem.

Techno-Entrepreneur: This is an individual who takes up a business endeavor that is focused on providing technology services and products with a staff strength of 2 to 100 employees.

Techno-Entrepreneurship: This is the process of creating new technological and internet driven businesses, products and services with the utmost goal of driving efficiency and high return on investment.

The ISO/IEC 29110 Software Lifecycle Standard for Very Small Companies

Rory V. O'Connor

 <https://orcid.org/0000-0001-9253-0313>

Dublin City University, Ireland

INTRODUCTION

Software development is a complex socio-technical activity and in earlier work we have examined the complex interaction between a software development process and its situational context (Clarke et al, 2015). Part of the challenge of organising the software development process involves deciding upon the specific roles involved in the process and the responsibilities of individuals fulfilling these roles. Therefore, just as the process itself is subject to regular change (Clarke et al, 2017) so too are the roles subject to change. We have therefore examined the role of the software engineer and how this has changed over time, including how it might change into the future.

Quality orientated software process approaches and standards have gained mainstream acceptance in the software development community over the year. There are many potential benefits of using standards due to the emphasizes on communication and having a shared common understanding of software lifecycle tasks.

For many small and start-up software companies, implementing controls and structures to properly manage their software development activity is a major challenge (Coleman & O'Connor, 2008c). It is commonly agreed that very small software companies, implementing management procedures, and controls to appropriately administer their software development activity is a significant challenge (Laporte et al, 2015). For example, a software company operating in Mexico may have a completely different set of operational problems when compared to a software company in the USA or Ireland. Even within a single geographical area such the range of operational issues faced by a small local firms can be radically different to those affecting a multinational subsidiary. The fact that all companies are not the same raises important questions for those who develop software process and process improvement models (Larrucea et al, 2016). To be widely adopted by the software industry, any process or process improvement model should be capable of handling the differences in the operational contexts of the companies making up that industry. But process improvement models, though highly publicized and marketed, are far from being extensively deployed and their influence in the software industry therefore remains more at a theoretical than practical level.

To help meet the need for VSE-specific systems and software lifecycle profiles and guidelines, the International Organization for Standardization and the International Electrotechnical Commission jointly published ISO/IEC 29110 “Lifecycle profiles for Very Small Entities” series of standards and guides, with the overall objective being to assist and encourage very small software organization in assessing and improving their software. These publications target VSEs, ranging from start-ups to grownups, with little or no experience or expertise in selecting the appropriate processes from systems or software engineering lifecycle standards (such as ISO/IEC/IEEE 12207) and tailoring them to a project’s needs (Laporte et. al, 2017).

DOI: 10.4018/978-1-7998-3473-1.ch103

The purpose of this chapter is to provide a primer on the ISO/IEC 29110 standard focusing on two main process areas of Project Management and Software Implementation. This chapter will start with an explanation of the rationale and justification for the development of this new standard, followed by an overview of its structure and explain how to deploy ISO/IEC 29110 in a typical very small software company.

BACKGROUND

This section will introduce the problem with standards and explain the specific case of very small entities, before presenting the ISO/IEC 29110 standard as a solution specifically designed to address these problems for very small companies.

Very Small Companies (VSE)

Due to the rich variety of software development settings (for example: the nature of the application being developed, team size, requirements volatility), the implementation of a set of practices for software development may be quite different from one setting to another (Jeners et al., 2013a). Small and very small companies are the fundamental growth of many national economies. It is important to notice that the contribution from the small companies should be seen as important and significant as compare to the large one (Jeners et al., 2013b).

The context for the development of the ISO/IEC 29110 series of standard was specifically that of Very Small Companies and it is therefore necessary to examine such terms. The definition of “Small” and “Very Small” Entities is challengingly ambiguous, as there is no commonly accepted definition of the terms. The term “Very Small Entity” (VSE) had been defined by the ISO/IEC JTC1/SC7 Working Group 24 and subsequently adopted for use in the new ISO/IEC 29110 software process lifecycle standard as being “an entity (enterprise, organization, department or project) having up to 25 people” (Laporte et al, 2008).

A large majority of enterprises worldwide are VSEs. In Europe, for instance, as illustrated in Table 1, over 92% of enterprises are micro-enterprises. They have fewer than nine employees. Micro enterprises account for 70% to 90% of enterprises in OECD countries and about 57% in USA.

Table 1. Size of enterprises in Europe (Moll 2013).

Type	Number of Employees	Annual turnover	No. of enterprises (% of overall)
Micro	1-9	≤2M	92.2
Small	10-49	≤10M	6.5
Medium	50-249	≤50M	1.1

Typically, VSEs are economically vulnerable as they are driven by cash flow and depend on project profits, so they need to perform the projects within budget. They tend to have low budgets which have many impacts, such as: lack of funds to perform corrective post-delivery maintenance; few resources allocated for training; little or no budget to perform quality assurance activities; no budget for software

reuse processes; low budget to respond to risks; and limited budget to perform Process Improvement and / or obtain a certification/assessment. Typically, the VSE's product has a single customer, where the customer is in charge of the management of the system and the software integration, installation and operation. It is normal practice for the customer not to define quantitative quality requirements and for customer satisfaction to depend on the fulfillment of specific requirements that may change during the project. A close relationship between all involved project members including the customer shows that software development in small and very small companies is strongly human-oriented and communication between them is important.

The internal business process of VSEs is usually focused on developing custom software systems, where the software product is elaborated progressively and which typically does not have strong relationship with other projects. Typically, most management processes (such as human resource and infrastructure management) are performed through informal mechanisms, with the majority of communication, decision-making and problem resolution being performed face-to-face.

Issues with Software Standards

Although commercial SPI models have been highly publicized, they are not being widely adopted and their influence in the software industry therefore remains more at a theoretical than practical level (O'Connor and Coleman, 2009). For example, in the case of Capability Maturity Model Integration (CMMI), an Australian study found that small organizations considered that adopting CMMI would be infeasible (Staples et al, 2007) and an Irish study found significant resistance due to negative perceptions surrounding levels of bureaucracy and required documentation (Coleman and O'Connor, 2006). Further investigation of the CMMI by Staples and Niazi (2006) discovered, after systematically reviewing 600 papers, that there has been little published evidence about those organizations who have decided not to adopt CMMI.

There is evidence that the majority of small and very small software organizations are not adopting existing standards / proven best practice models because they perceive the standards as being developed by large organizations and orientated towards large organizations, thus provoking the debate in terms of number of employees, size does actually matter (O'Connor and Coleman, 2008a). Studies have shown that small firms' negative perceptions of process model standards are primarily driven by negative views of cost, documentation and bureaucracy. In addition, it has been reported that SMEs find it difficult to relate standards to their business needs and to justify the application of the international standards in their operations. Most SMEs cannot afford the resources for, or see a net benefit in, establishing software processes as defined by current standards and maturity models (O'Connor and Coleman, 2008b).

The ISO/IEC 29110 Standard as a Solution

Accordingly there is a need to help such organizations understand and use the concepts, processes and practices proposed in the ISO/IEC JTC1/SC7's international software engineering standards. The ISO/IEC 29110 standard "Lifecycle profiles for Very Small Entities" is aimed at addressing the issues identified above and addresses the specific needs of VSEs. The approach (Laporte et al, 2013a) used to develop ISO/IEC 29110 (2001) started with the pre-existing international standard ISO/IEC 12207 (2008) dedicated to software process lifecycles. The overall approach consisted of three steps: (1) Selecting ISO/IEC 12207 process subset applicable to VSEs of up to 25 employees; (2) Tailor the subset to fit VSE needs; and (3) Develop guidelines for VSEs.

Furthermore, in late 2009, the International Council on Systems Engineering (INCOSE) Very Small and Micro Entities Working Group (VSME) was established to evaluate the possibility of developing a standard, using the Generic profile group scheme of the ISO/IEC 29110 series, based on ISO/IEC 15288 (2008), for organizations developing systems. Late 2011 saw the launch of the official development of the systems engineering ISs and TRs for VSEs. In August 2014, ISO published the ISO/IEC 29110 systems engineering and management guide of the Basic profile ISO/IEC TR 29110-5-6-2:2014 (2014). The systems engineering and management guide of the Entry profile has been published in 2015 as ISO/IEC TR 29110-5-6-1:2015 (2015). Similar to the existing set of software ISO/IEC 29110 TRs, the Management and Engineering Guide for systems engineering should also be made available at no cost by ISO (Laporte et al, 2014).

For example a more recent study (Sánchez-Gordón and O'Connor, 2016). Understanding into software developers' use of software development processes in actual practice in the specific context of very small companies and highlighted three areas of concern: customer, software product and development tasks coordination and tracking, where small companies were lacking specific guidance (Sanchez-Gordon et al, 2017).

A full history of the evolution of the ISO/IEC 29110 series of software process lifecycle standards is given in O'Connor & Laporte (2017).

The Structure of ISO/IEC 29110

The basic requirements of a software development process are that it should fit the needs of the project and aid project success. And this need should be informed by the situational context (Marks et al, 2017) where in the project must operate and therefore, the most suitable software development process is contingent on the context. The core situational characteristic (Clarke and O'Connor, 2012) of the entities targeted by ISO/IEC 29110 is size, however there are other aspects and characteristics of VSEs that may affect profile preparation or selection. Creating one profile for each possible combination of values of the various dimensions introduced above would result in an unmanageable set of profiles. Accordingly, VSE's profiles are grouped in such a way as to be applicable to more than one category. Table 2 illustrates a Profile Group, which contains three profiles (labeled A, B and C) that are mapped to nine combinations of business models and situational factors (Giray et al, 2018).

Table 2. Allocating VSE characteristics to profile groups.

Business Models	Profile Situational Factors		
	Critical	User Uncertainty	Environment Change
<i>Contract</i>	<i>Profile A</i>	<i>Profile A</i>	<i>Profile A</i>
<i>In-House</i>	<i>Profile C</i>	<i>Profile B</i>	<i>Profile A</i>
<i>Commercial</i>	<i>Profile B</i>	<i>Profile A</i>	<i>Profile A</i>

Profile Groups are a collection of profiles, which are related either by composition of processes (i.e. activities, tasks), or by capability level, or both. The “Generic” profile group is applicable to a vast majority of VSEs that do not develop critical software and have typical situational factors (Clarke & O'Connor, 2015). This profile group does not imply any specific application domain, however, it is envisaged that in the future new domain-specific sub-profiles may be developed in the future. Table 3

illustrates this profile group as a collection of four profiles, providing a progressive approach to satisfying the requirements of profile group. To date the Basic Profile has been published, the purpose of which is to define a software development and project management guide for performing one project at a time.

Table 3. Graduated profile of the Generic profile group.

Engineering and Management Guide

At the core of this standard is a Management and Engineering Guide, officially known as ISO/IEC TR 29110-5-1-2 (2011), which focuses on *Project Management* and *Software Implementation* as illustrated in figure 1. The purpose of the Basic Profile is to define Software Implementation (SI) and Project Management (PM) processes from a subset of ISO/IEC 12207 (2008) and ISO/IEC 15289 (2011) appropriate for VSEs, as illustrated in figure 1.

Figure 1. ISO/IEC 29110 Project Management and Software Implementation Relationship.

Project Management Process

The purpose of the Project Management (PM) process is to establish and carry out the tasks of the software implementation project in a systematic way, which allows compliance with the project's objectives in terms of expected quality, time, and costs (O'Connor and Laporte, 2012). The seven objectives of the PM process are listed in table 4.

Table 4. Objectives of the Project Management process of the Basic Profile (ISO/IEC TR 29110-5-1-2 (2011)).

Objective	Description
PM.O1	The Project Plan for the execution of the project is developed according to the Statement of Work and reviewed and accepted by the Customer. The tasks and resources necessary to complete the work are sized and estimated.
PM.O2	Progress of the project is monitored against the Project Plan and recorded in the Progress Status Record.
PM.O3	The Change Requests are addressed through their reception and analysis. Changes to software requirements are evaluated for cost, schedule and technical impact.
PM.O4	Review meetings with the Work Team and the Customer are held. Agreements are registered and tracked.
PM.O5	Risks are identified as they develop and during the conduct of the project.
PM.O6	A software Version Control Strategy is developed. Items of Software Configuration are identified, defined and baselined. Modifications and releases of the items are controlled and made available to the Customer and Work Team including the storage, handling and delivery of the items.
PM.O7	Software Quality Assurance is performed to provide assurance that work products and processes comply with the Project Plan and Requirements Specification.

Figure 2 illustrates the 4 activities of the project management process as well as their input and output product. The four activities of the Project Management Process are:

- **Project Planning** - The primary objective of this process is to produce and communicate effective and workable project plans. This process determines the scope of the project management and technical activities, identifies process outputs, project tasks and deliverables, establishes schedules for project task conduct, including achievement criteria, and required resources to accomplish project tasks.
- **Project Plan Execution** - To implement the actual work tasks of the project in accordance with the project plan. Ideally when the project plan has been agreed and communicated to all teams members, work of the development of the product, which is the subject of the project, should commence.
- **Project Assessment and Control** - purpose is to determine the status of the project and ensure that the project performs according to plans and schedules, within projected budgets and it satisfies technical objectives.
- **Project Closure** - typically involves releasing the final deliverables to the customer, handing over project documentation to the business, terminating supplier contracts, releasing project resources and communicating project closure to all stakeholders.

For illustration purposes, two tasks of the Project Planning activity are listed in Table 5. The project manager (PM) and the customer (CUS) are involved in these 2 tasks. The customer is involved, during

Figure 2. ISO/IEC 29110 Project Management Process.

Table 5. Example of 2 tasks of the Project Planning Activity (ISO/IEC TR 29110-5-1-2 (2011)).

Role	Task	Input	Output
PM CUS	PM.1.2 Define with the Customer the Delivery Instructions of each one of the Deliverables specified in the Statement of Work.	Statement of Work [reviewed]	Project Plan Delivery Instructions
PM CUS	PM.1.14 Review and accept the Project Plan. Customer reviews and accepts the Project Plan, making sure that the Project Plan elements match with the Statement of Work.	Project Plan [verified]	Meeting Record Project Plan [accepted]

the execution of the project, when he submits change requests, during project review meetings, for the validation and approval of the requirements specifications and for the acceptance of the deliverables.

Software Implementation Process

The purpose of the Software Implementation (SI) process, illustrated in figure 3, is to achieve systematic performance of the analysis, design, construction, integration, and test activities for new or modified software products according to the specified requirements. The seven objectives of the SI process are listed in table 6.

Table 6. Objectives of the Software Implementation process of the Basic Profile.

Objective	Description
SI.O21	Tasks of the activities are performed through the accomplishment of the current Project Plan.
SI.O2.	Software requirements are defined, analyzed for correctness and testability, approved by the Customer, baselined and communicated.
SI.O3.	Software architectural and detailed design is developed and baselined. It describes the Software Components and internal and external interfaces of them.
SI.O4.	Software Components defined by the design are produced. Unit test are defined and performed to verify the consistency with requirements and the design. T
SI.O5.	Software is produced performing integration of Software Components and verified using Test Cases and Test Procedures. Results are recorded at the Test Report.
SI.O6.	A Software Configuration, that meets the Requirements Specification as agreed to with the Customer, which includes user, operation and maintenance documentations, is integrated, baselined and stored at the Project Repository.
SI.O8.	Verification and Validation Tasks of all required work products are performed using the defined criteria to achieve consistency among output and input products in each activity.

The activities of the Software Implementation Process are:

- **Software Implementation Initiation** - ensures that the Project Plan established in Project Planning activity is committed to by the Work Team
- **Software Requirements Analysis** - analyzes the agreed Customer's requirements and establishes the validated project requirements. The activity provides:
- **Software Architectural and Detailed Design** - transforms the software requirements to the system software architecture and software detailed design
- **Software Construction** - develops the software code and data from the Software Design.
- **Software Integration and Tests** - ensures that the integrated Software Components satisfy the software requirements.
- **Product Delivery** - provides the integrated software product to the Customer.

Figure 3. ISO/IEC 29110 Software Implementation Process.

IMPLEMENTING THE ISO/IEC 29110 STANDARD

Guidance on Implementation

In order to facilitate the implementation, by VSEs, of a Profile, a set of Deployment Packages (2013) are available. A deployment package is a set of artifacts developed to facilitate the implementation of a set of practices, of the selected framework, in a VSE. A deployment package is not a process reference model (i.e. it is not prescriptive). The elements of a typical deployment package are: description of processes, activities, tasks, roles and products, template, checklist, example, reference and mapping to standards and models, and a list of tools. Deployment packages are not intended to preclude or discourage the use of additional guidelines that VSEs find useful.

The elements of a typical deployment package are: technical description, relationships with ISO/IEC 29110, key definitions, detailed description of processes, activities, tasks, roles and products, template, checklist, example, references and mapping to standards and models, and a list of tools. The mapping is only given as information to show that a Deployment Package has explicit links to Part 5, ISO standards, such as ISO/IEC 12207, or models such as the CMMI developed by the Software Engineering Institute. Hence by deploying and implementing a package (O'Connor and Sanders, 2013) a VSE can see its concrete step to achieve or demonstrate coverage to Part 5.

The working group (ISO/IEC JTC1/SC7 WG 24) behind the development of this standard is advocating the use of pilot projects as a mean to accelerate the adoption and utilization of ISO/IEC 29110. Pilot projects are an important means of reducing risks and learning more about the organizational and technical issues associated with the deployment of new software engineering practices. Pilot projects are based on the ISO/IEC 29110-5 Management and engineering guide and the deployment package(s).

Sample Implementations

Worldwide, hundreds of VSEs have implemented ISO/IEC 29110. For instance, in Thailand, an early adopter of ISO/IEC 29110, more than 350 public and private organizations have achieved the ISO/IEC 29110 Basic Profile certification. In addition, 33 other VSEs are certified in other states of Mexico in the state of Zacatecas in Mexico, industry, academia, and government came together in 2017 to promote ISO/IEC 29110 (Laporte et. al, 2016). In Zacatecas, approximately four Mexican VSEs and four software development centers of academic institutions are certified for the Basic Profile. In addition, 33 other VSEs are certified in other states of Mexico. Researchers in Canada have led numerous field trials with early-stage adopters of ISO/IEC 29110 (Laporte et. al, 2017).

For example, Ribaud et al. (2010) have documented the results of one pilot project that conducted with a 14-person VSE based in France, which successfully implemented ISO/IEC 29110 processes practices utilizing the available Deployment Packages. From which they have identified some potential additional infrastructure and support process activities and suggestions for future evolution of ISO/IEC 29110 Process Profiles. A further series of pilot projects are currently underway in research laboratories and enterprises in Canada, Ireland, Belgium and France, with further pilot projects planned in the near future.

The results from one pilot study in Canada concluded that the tools developed to support the project management processes proved very useful and helped the project managers rapidly integrate the knowledge required to execute the processes (Laporte et al, 2013b). In the case of this trial company, for the first time, the company has documented management processes for small-scale projects. Besides, some project managers have joined forces to promote project management practices within this engineering firm's division. The improvement programme was so successful that managers of the company's other divisions have shown an interest in learning this approach in order to implement it within their respective divisions.

Laporte et al (2015) report on two successful trials of ISO/IEC 29110, that demonstrate it was possible to properly plan the project and develop the software product using proven software practices documented in standards as well as not interfering with the creativity during the development of their web site. People who think that standards are a burden, an unnecessary overhead and a treat to creativity should look at this start-up project and revisit their results.

VSEs that have implemented ISO/IEC 29110 management and engineering guides have improved in one or more aspects of competitiveness including quality, cost, and schedule (Laporte & O'Connor, 2016). For example, projects using ISO/IEC 29110 for the first time had only 10 to 18 percent of rework as opposed to about 40 to 50 percent of rework typical of a majority of software developers (Laporte & O'Connor, 2017).

CONCLUSIONS

For most enterprises, but in particular for VSEs, international certifications can enhance credibility, competitiveness and access to national and international markets. Brazil has led the development of an ISO/IEC 29110 certification process. An ISO/IEC 29110 auditor should be competent in auditing techniques, have expertise in ISO/IEC 29110 and have experience in software development. For VSEs, such a certification should not be too expensive and short. The certification process has been successfully piloted in a few VSEs.

Finally, research studies have been undertaken to understanding the perception of VSEs towards the adoption of process standards (Basri et al, 2010) (O'Connor & Basri, 2018.) and also to evaluate management sentiment towards ISO/IEC 29110 (O'Connor, 2012) and management commitment to SPI and ISO/IEC 2910 in particular in Europe (O'Connor et al, 2010) and South America (Sanchez-Gordon et al, 2015). These revealed that the acceptance level of any type or model of software quality or lifecycle standard in VSEs is a very low priority item, but the level of awareness of standards and potential benefits was high. Furthermore, these studies showed the main reason for not adopting standards was a lack customer requirement, a lack of resources and the perceived difficulties in defining an organizational process. Furthermore, this analysis reveals a pattern that indicates that the acceptance level of quality standard such as ISO among VSEs are still low even though the staff and management are knowledgeable and aware the benefit of adopting such standards. The main reasons are more related to the lack of the customer requirement and the limited resources in the company. In addition, the perception a heavy-weight process especially in terms of documentation, cost and non- alignment with current development process are among the reasons why the companies did not plan to adopt a lifecycle standard in the short to medium term. However from the analysis, VSEs may still be interested in lifecycle standards if certain important criteria are met and such standards are closely related to their needs. Therefore, it can be concluded that the market and demand for ISO/IEC 29110 in VSEs has a positive outlook.

Future Research

In terms of future work, as ISO/IEC 29110 is an emerging standard there is much work yet to be completed (O'Connor and Laporte, 2014). The main remaining work item is to finalize the development of the remaining three profiles: (a) Entry – a six person-months effort project or a start-up VSEs; (b) Intermediate - Management of more than one project and (c) Advanced - business management and portfolio management practices. In addition, the development of additional Profile Groups for other domains such as critical software, game industry, scientific software developments are being studied.

Whilst work is currently underway on an assessment mechanism for ISO/IEC 29110, a clear niche market need is emerging which may force the process assessment community to change their views on how process assessments are carried out for VSEs. In particular there is a strong need to ensure that VSEs are not required to invest the anything similar in terms of time, money and other resources on process assessments, as may be expected from their larger SMEs (small and medium enterprises), or even MNC (multinational corporations) counterparts. Indeed, some form of self-assessment, possibly supported by Internet based tools, along with periodic spot-checks may be suitable alternative to meet the unique needs of VSEs.

Furthermore, work is underway to integrate accessibility design patterns with the software implementation process of ISO/IEC 29110 (Sanchez-Gordon et al, 2019) and to examine the impact of cultural issues on the software process of very small entities (Nonoyama et al, 2018). Also, from an agile pro-

cess perspective, research is being conducted into the compliance of the ISO/IEC 29110 Entry Profile with the Project Management process in the main agile methodologies (Galvan-Cruz et al, 2017a) and SCRUM in particular (Galvan-Cruz et al, 2017b). Finally, the area of serious games (Olgun et al, 2017) is being applied to the ISO/IEC 29110 and ISO/IEC 29110 project management process of basic profile (Calderón et al 2017).

KEY TERMS AND DEFINITIONS

Process Assessment: The disciplined examination of the processes by an organisation against a set of criteria to determine capability of those processes to perform within quality, cost and schedule goals.

Project Implementation: Is defined as a specified set of activities designed to put into practice an activity or program of known dimensions.

Project Management: This is the process and activity of planning, organizing, motivating, and controlling resources to achieve specific goals.

Software Process: A set of activities, methods, practices, and transformations that people use to develop and maintain software and the associated products.

Software Process Improvement (SPI): Aims to understand the software process as it is used within an organisation and thus drive the implementation of changes to that process to achieve specific goals such as increasing development speed, achieving higher product quality or reducing costs.

Very Small Entity: An enterprise, organization, department, or project having up to 25 people.

Design of a Strategic Knowledge Management Model to Evaluate Sales Growth in SMEs

Leonardo Bermon-Angarita

National University of Colombia, Colombia

Lyda Jovanna Rueda-Caicedo

National University of Colombia, Colombia

INTRODUCTION

The increasing importance of knowledge as an intangible asset or intellectual capital (CI) for companies, has encouraged managers to pay greater attention to knowledge management (KM) strategies (Hansen, Nohria & Tierney, 1999; Earl, 2001), allowing companies to capture, conserve, organize and manage the knowledge and experiences that are generated, for further dissemination and maintenance of sustainable development, through the use of the acquired IC (Nonaka & Takeuchi, 1995; Pasternack & Viscio, 1998; Pfeffer & Sutton, 1999; Ruggles & Holtshouse, 1999).

Although there is evidence that large companies have invested in initiatives and information systems for KM, which enables them acquiring and improving the use of IC (Sarvary, 1999). However, previous studies have shown that in many SMEs there is an absence of systematic KM (McAdam & Reid, 2001; Wong & Aspinwall, 2005). This fact is supported on some other studies that have identified some factors leading to this absence, such as SME managers assume a central position (Bridge, O'Neill & Cromie, 2003), thus limiting the planning and decision-making processes to a single person (Culkin & Smith, 2000). Therefore, it is shown that some SMEs fail to identify knowledge as an intangible business asset. Which like any other asset, must be valued, processed and be systematically organized, since only people (such as competitors, customers, suppliers, vendors, etc.) are the only agents capable of learning and creating knowledge in an organization, through their individual and collective experience.

Therefore it could be inferred that companies, whether large or small must have continuous learning as a process for the organization to identify its best practices, in order to avoid repeating errors and producing a decrease in entropy (Sharma et al., 2007). Senge (1990) states that organizational learning occurs when people frequently increase their ability to create in order to achieve objectives, designing new patterns for distributing thought and also, where people are continuously learning observing the whole process. In addition to that, Senge affirms that when an organization learns, it can be defined as groups of people that collaborate with each other, to collectively strengthen their capacities and achieve truly important results. According to this, the learning process must start from management, identifying knowledge as a critical element in business strategies. Fernández, Junquera & Del Brio (2009) pointed out that the competitive advantage is not within the individual as a generator and a possessor of knowledge, but in the ability of the company to transfer personal knowledge to different contexts, integrating it into the routines and foundations of the organization, in order to improve its innovative capacity, to achieve a sustainable competitive advantage. Consequently, the success of business learning is based

DOI: 10.4018/978-1-7998-3473-1.ch104

on the transformation of the knowledge related to human and relational capital (tacit knowledge) into knowledge of structural capital (explicit knowledge) (Sharma et al., 2007).

Consequently, being business success directly related to growth, especially to sales growth, this responsibility is in general delegated to the marketing department, which is responsible for developing and implementing strategies necessary to achieve the company's objectives; but: Is it possible to measure the level of growth in sales of an SME through the implementation of a KM strategy? The objective of this paper is to answer this question, through the study of the variables that intervene in the generation of knowledge in the marketing area, specifically in the internal KM between the sellers and the management personnel, proposing a KM model that can be implemented by the management personnel.

This paper is organized as follows: First, a background of the papers related to the research topic is carried out. Next, the methodology that was used is presented describing the hypothesis, research design, data collection instruments, and the description of the design of the model. Then, the results are shown with an analysis of descriptive data, multiple regression and correlations. After that, some future research directions are proposed. Finally, the conclusions of the paper are stated.

BACKGROUND

For the construction of this study, some tools were used to obtain a clearer answer of the evolution of KM and its different perspectives, such as these two electronic resources: *Web of Science* and *Tree of Science* (Robledo, Osorio & Lopez, 2014) as well as this search string, that was used in the Web of Science:

The first search title was: (*knowledge management*) AND subject: (*intellectual capital enterprises*) Refined by: Web of Science categories: (*Management or Business or Operations Research Management Science*) AND Document types: (*Article or Proceedings Paper*) Period of time: 2009-2018. Indexes: *SCI-EXPANDED, SSCI, A & HCI, ESCI*.

From this search, we obtained 367 results, which were the basis to us the *Tree of science* (ToS) tool, in order to build the state of the art from the searches carried out in WoS. Since the ToS algorithm is based on graph theory, the papers are represented as nodes and the citations between them as links. In this way, each node represents a knowledge unit located within the network. The most important nodes are identified from their determined positions, according to the links that connect to other nodes. Therefore, the papers located in the root are the most cited on the KM subject, the papers of the trunk are the papers that quote the root and are cited in the leaves. Finally, the leaves are papers that cite both: the root and the trunk. In this way, scientific information can be visualized in the form of a tree (Robledo, Osorio & Lopez, 2014).

Once this structure is finished, the most important papers of each part of the tree are analyzed and selected, choosing only from three to five papers in each area. This visualization allows us to have an overview of the theoretical foundation and current developments on the knowledge management, aiming to fulfill the main objective of the research.

With the results obtained in ToS, it was possible to chronologically select and organize the literature related to the research topic, analyzing the most important concepts of knowledge management.

The papers located on the root of the ToS can help identifying a type of research that allows conceptualizing the two types of knowledge. First, Tacit knowledge, which refers to valuable and highly subjective ideas and intuitions that are difficult to grasp and share because people have them in their minds. Secondly, Explicit knowledge which can be expressed through formal language by using words and numbers, and can be easily transmitted and shared through data, scientific formulas, codified proce-

dures or universal principles, being usually expressed in some physical support (Polanyi, 1966; Nonaka, Byosiere, Borucki & Konno, 1994).

From the differentiation of these two types of knowledge, the spiral model was designed (Nonaka et al., 1994) leading to four basic ways of knowledge creation in a company, which are: socialization, externalization, combination and internalization. Socialization is when a member of the group starts with the creation of a new knowledge; Externalization is a dialogue or collective reflection, which is made by using appropriate metaphors or analogies; Combination is the distribution of knowledge made through the different social and organizational networks; and Internalization is how knowledge begins to spread throughout the organization, causing other employees to start using it and internalizing it, so they can use it to expand their tacit knowledge.

Some of the papers on the root show antecedents, definitions and elements that conform the notion of intellectual capital (Edvinsson & Sullivan, 1996). Some of these papers also show the importance of intellectual capital or intangible asset, as a competitive advantage in organizations and how to measure it, taking as an example the Swedish financial services company Skandia, which in 1995 published the IC's first annual report (Edvinsson & Malone, 1997). Likewise, within research, the KM is incorporated as a discipline that reveals that in practice, only the 20% of the knowledge available in the company is used. The aforementioned opened a space for greater efficiency, growth, benefits and competitive margin, making the intellectual capital of the company grow (Stewart, 1997; Brooking, 1997; Lynn, 1999). Hence, three dimensions of the IC are identified:

- Human capital: Defined as a generator of value and a potential source of innovation for the company (Bontis, 1998).
- Structural capital: It is the knowledge that the company has been able to internalize and that remains in the organization, whether in its structure, in its processes or in its culture, even when the employees leave it (Bontis, Chua & Richardson, 2000).
- Relational capital: Draws on the consideration that companies are not isolated systems, on the contrary, they are related to the outside world. This type of capital includes the value generated by the company's relationships, not only with customers, suppliers and shareholders, but with all its stakeholders, both internal and external (Bontis et al., 2000; Stewart, 1997; Ordóñez, 2003; Alavi & Leidner, 2001; Bartol & Srivastava, 2002).

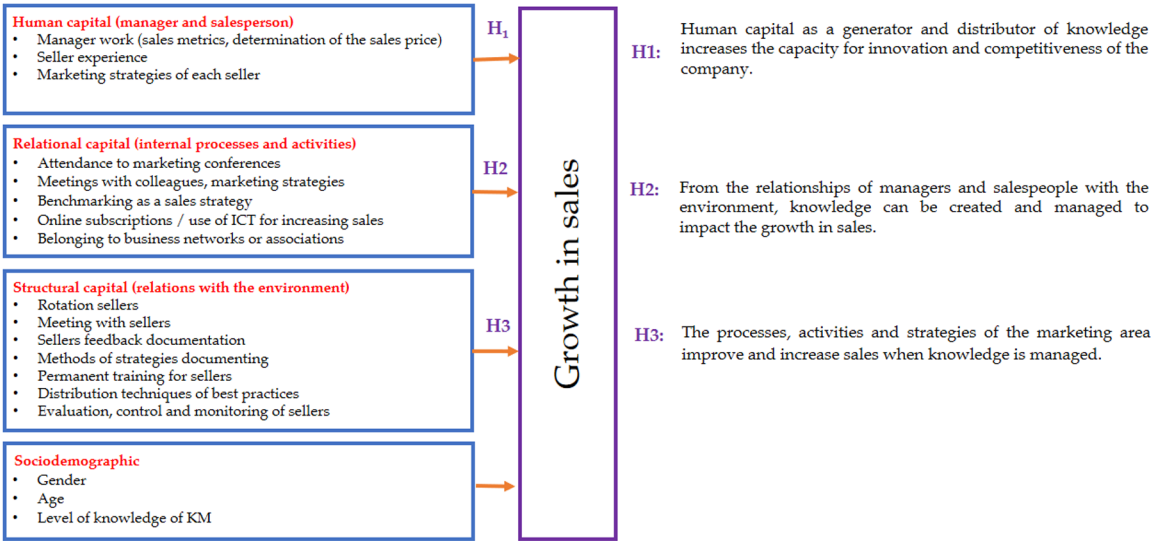

As for the papers that are on the trunk, it could be stated that they give solidity to the theory of KM from different perspectives. For example, Bollinger and Smith (2001) proposed that human behavior is key for achieving success or failure of KM activities, since KM implies culture, teamwork, promotion of learning and the exchange of skills and experiences. DeTienne, Dyer, Hoopes & Harris (2004) and Mehta (2008), identified technical factors as key elements in an effective KM. Some papers examine models of KM systems constructed as a measure of how context knowledge exchanges and reuses activities, that are internalized by organizations (Kulkarni, Ravindran & Freeze, 2006). Other studies such as the case of (Hsu & Wenchang, 2009) show the relationship between intellectual capital and organizational learning capacity in the development of new products, through the use of interviews and surveys. The results were based on empirical data from Taiwan's IC design industry, which are generated by the method of partial least squares. Likewise, authors such as (Donate & Guadamillas, 2011) analyze how organizational factors such as cultural values, leadership and human resources practices influence the practices of exploration and exploitation of knowledge, as well as innovation through empirical study.

In the part of the leaves, there are researches which unify criteria such as KM encompasses processes and structures, used by companies to support different stages of knowledge, such as: transfer, storage and creation (Durst & Edvardsson, 2012). Additionally, there are other research projects that show designs/implementations of delimited KM systems, taking into account: the size and the specific sector of the company; the research approach (competitiveness, innovation or process improvement) and the type of knowledge conversion. An example of this type of research was the one carried out by Burton, O'Connor & Roos (2013) involving five manufacturing companies, that participated in a series of action learning workshops and particularly, in the workshop focused on using the IC Navigator approach. The aforementioned study examines the utility of this model as a tool, to reconfigure the resources of a company, taking into account the results and the perception of the five companies under study. Other research pointed in this part seeks to update a global classification of academic journals of knowledge management and intellectual capital, as is the case of Serenko, A. & Bontis (2017).

METHODOLOGY

This study defines three hypotheses to be demonstrated (see Figure 1).

Figure 1. Hypothesis

- Hypothesis 1: Human capital as a generator and distributor of knowledge increases the capacity for innovation and competitiveness of the company.

To demonstrate this hypothesis, the human capital of the company specifically the manager and the salespeople, will be studied. From the perspective of management, variables such as sales metrics and sales price determination are included. From the seller's perspective, variables such as the seller's experience and the marketing strategies of each seller are included.

- Hypothesis 2: From the relationships of managers and salespeople with the environment, knowledge can be created and managed to impact the growth in sales.

To demonstrate this hypothesis, the relational capital (internal processes and activities) will be studied, taking into account the attendance to marketing conferences, meetings with colleagues, establishment of marketing strategies, benchmarking as a sales strategy, online subscriptions / use of ICT for increasing sales and also, belonging to some type of business network or association.

- Hypothesis 3: The processes, activities and strategies of the marketing area improve and increase sales when knowledge is managed.

In order to demonstrate this hypothesis, the structural capital (relations with the environment) was studied through variables such as sales agents, meeting with sellers, documentation of the sellers' feedback, methods of strategies documenting, permanent training to sellers, distribution techniques of best practices and evaluation, control and monitoring of sellers.

KM studies are approached with both, quantitative and qualitative approaches. In this study, a qualitative approach was the fundamental core, integrating quantitative data from the information collection instruments. The quantitative research allowed a rigorous treatment of the information and the statistical processing of the obtained data. The objective of this study is to design a KM strategy in the marketing area, to evaluate the growth in sales in SMEs.

The data collection was done through surveys, like this: First, a sample of SMEs must be selected from a certain city. For selected SMEs, a survey was developed to measure the level of knowledge and application of techniques aimed at KM in the marketing area. Then, a SME was selected as an object of study, where its manager was interviewed with closed questions about the internalization process of marketing knowledge, taking into account aspects such as: resources used by their best sellers, knowledge of the competition, specific marketing techniques, perception of the product / service to be sold, experience of sellers and customers, use of technological tools and relations with customers.

Through this study, it was expected to define a set of independent variables and a dependent variable. The dependent variable corresponds to the total of sales (Y) that is defined as the total amount of money obtained from the sale of products / services of a SME.

The independent variables are related to knowledge management, since they are strategies oriented to the conversion of knowledge such as: rotation sellers (X_1); meeting with sellers (X_2); documentation feedback sellers (X_3); attendance to conferences related to marketing (X_4); meetings with colleagues to establish marketing strategies (X_5); use of benchmarking as sales strategy (X_6); permanent sales training (X_7); online subscriptions and use of ICT to increase sales (X_8); documentation of marketing policies of the company (X_9); identification of marketing strategies used by sellers (X_{10}); documentation methods used in the company (X_{11}); existence of a model of metrics (X_{12}); full confidence in the experience of the seller (X_{13}); the company belonging to some type of business network or association (X_{14}); importance of the product price in sales (X_{15}); distribution techniques of best practices (X_{16}); and, evaluation, control and monitoring to sellers (X_{17}).

The model that relates the independent variable with the identified dependent variables is:

$$Y = A_1 * X_1 + A_2 * X_2 + A_3 * X_3 + A_4 * X_4 + A_5 * X_5 + A_6 * X_6 + A_7 * X_7 + A_8 * X_8 + A_9 * X_9 + A_{10} * X_{10} + A_{11} * X_{11} + A_{12} * X_{12} + A_{13} * X_{13} + A_{14} * X_{14} + A_{15} * X_{15} + A_{16} * X_{16} + A_{17} * X_{17}$$

Where

Y = Is the Total of sales

X_i = Are the Independent variables

A_i = Are the Weights of influence of the independent variables regarding to sales.

RESULTS

For the analysis of results, it was used a multiple regression model in R (software for statistical data analysis). The results that were obtained will be explained as follows: first, there is an analysis of the descriptive statistical data; then, we can find the correlations and degree of significance or reliability between variables; after that, there are displayed the results of the multiple regression analysis; and finally, we can see the strategic model that is proposed based on the hypothesis test.

Analysis of Descriptive Statistical Data

A diagnostic survey was conducted with a 1000 marketing managers of SMEs through Internet, the 30% of this population were women and the 70% men. The average age of the respondents was 40 years old, with age ranges from 35 to 44 years old, according to the standard deviation. In this analysis there were considered the following perspectives: management and their perception of knowledge management; seller as knowledge generators; and a statistical graph to identify the strategy that was most frequently used, to generate knowledge regarding marketing.

Figure 2. Means, standard deviations and correlations with intervals of significance or reliability

Note. * indicates $p < 0.05$; ** indicates $p < 0.01$. M and SD are used to represent the mean and the standard deviation, respectively. The values in brackets indicate the 95% confidence interval for each correlation. The confidence interval is a plausible range of population correlations that could have caused the sample correlation.

1. Management and their perception of KM:

Figure 2 shows the mean, the standard deviation, the correlation and the degree of significance between variables.

From this survey, we see that 50% of respondents said they had heard about KM. The answers of the rest of the respondents dispersed among managers who did not know about the topic, and managers for whom KM concepts were familiar, but they did not apply them in their company (variable *concepts.management*). Only 29% of the managers surveyed document the feedback information with their sellers, but taking into account the standard deviation that they do not perform it frequently (variable *documentation*). The 79% of managers document the strategies or marketing policies of their companies (variable *strategies.marketing*).

The 80% of managers prefer to have written documentation, physically filed, of marketing processes and strategies (variable *methods.documentation*). The 79% of the SMEs surveyed belong to a group or business association (variable *network.organizational*). When asking managers to value from 1 to 5 the degree of influence that the price has on sales, this was a 4.3 (variable *price*). The 63% of managers do not apply knowledge distribution techniques in their company (variable *techniques.distribution*).

2. The management - Seller relationship as generators of knowledge:

The survey showed that the sellers turnover rate is high (60%) and taking into account the standard deviation, this rate ranges between the 55% and the 65% (variable *sellers.turnover*). It was also observed that, the frequency of meetings between management and sellers is once a week, although dispersion is usually present in these meeting periods (daily, weekly or biweekly) according to standard deviation (variable *meetings.colleagues*). Only 29% of managers know the marketing strategies or best practices carried out by their salespeople (variable *strategies.sellers*). The 79% of managers have evaluation criteria (metrics) to measure the performance of their salespeople (variables *metric.sales*), but only the 42% make this evaluation effective (variable *evaluate.sales*).

3. Statistical figure to identify the most frequently used strategy to generate knowledge in marketing:

Figure 3 shows that, the most frequently used strategy for acquiring knowledge in marketing is sales training. But, most of the time the managers trust and discharge the responsibility of sale in the empirical experience of the sellers. In most cases, managers attend to conferences to be aware of marketing trends. Half of the time, managers use benchmarking tools or attend meetings with colleagues, to learn about the best marketing strategies. Sometimes or almost never, they make use of online subscriptions as a learning tool.

Correlations and Degree of Significance or Reliability Between Variables

In Table 1, it is observed that despite there is a low degree of correlation (r) between the variables, there are significant relationships in the correlations between variables, because p -value takes values less than .05; allowing the selected sample to be valid for this research. Table 2 indicates that, there is a 79% of positive correlations between variables (values indicated with normal text) being $0 < r < 1$. And a 21% of negative correlations between variables (values indicated with cursive) being $-1 < r < 0$ between variables. In both cases, although the degree of correlation is low, the degree of significance is high. It

Figure 3. Statistics on KM strategies in marketing

Table 1. Correlations and significance between variables

Variables	sales	strategies.sellers	documentation	price	methods.documentation	metrics.sales	evaluate.sales
concepts.management	.09**	.06*	.08*				.07*
turnover.sellers	.70**	.07*		.06*			
meetings.sales	.12**				-.07*		
attendance.conferences	.09**						
benchmarking	.21**						
training.sellers	.07*	.07*					
experience.sellers	.08*						
subscriptions	.18**	-.07*					
strategies.marketing	.08**						
strategies.sellers	.10**					.08*	
techniques.distribution	.12**						
gender							.07*
age				.07*			
price							-.10**

Note. * indicates $p < 0.05$; ** indicates $p < 0.01$. Values that indicate the degree of significance or reliability for each correlation.

is also observed that the sales variable is the one that most relates to the rest of the variables; and it is also noted that the highest correlation is between the *sales* variable and the *seller's turnover* variable, with a significant correlation level of .70 **.

Results of the Multiple Regression Analysis

The influence of the independent variables and the standardized regression (beta weights) is showed on Table 2.

Table 2. Regression results using uncertainty as a criterion

Therefore, we have that:

- a) Influence of the independent variables: Taking into account the value of $p < .05$, the independent (explanatory) variables that are significantly related to the sales dependent variable were selected. These variables are: *gender*, *meeting.sales*, *assistance.conferences*, *meetings.colleagues*, *training.sellers*, *experience.sellers*, *subscriptions*, *strategies.marketing*, *network.business*, *price*, *techniques.distribution*, *evaluation.sales*.
- b) Beta standardized regression weights: Of the independent variables selected, the one that most influences or explains the behavior of sales is the *price* variable (-0.23), because it is the furthest one from zero. The negative sign indicates that the lower the price of the products is, the greater the increase in sales is. Other relevant variables, in the behavior of the sales dependent variable are: *meeting.sales* (-0.21), which means that the fewer the meetings are with the salespeople, the higher the sales will be. This result seems to be counterintuitive, but it could be explained from the view that when managers perceive that the sales are representative, they do not require meetings with the sellers. *Training.sellers* variable (0.18) implies that the greater the salespersons are trained, the greater the sales are. *Subscriptions* variable (-0.16) means that the lower online subscriptions are, the lower the sales are. This behavior could be explained from the perspective that management does not consider ICT as a sales-generating element. *Attendance.conference* variable (0.15) implies that the more attendance of managers and salespeople to conferences related to marketing is, the greater the sales are. *Techniques.distribution* variable (0.14), which means that the greater the distribution of knowledge and best practices within the company are, the greater the increase on sales is. *Evaluate.sales* variable (-0.14) implies that sellers are evaluated less when the company's sales increase. *Strategies.marketing* variable (0.13), when the marketing strategies are improved, the sales increase. *Experience.sellers* variable (-0.12), when the responsibility for sales lies solely in the experience of sellers, sales tend to decrease. This could be interpreted as requiring other control and monitoring strategies for sellers. *Gender* variable (-0.07), this means that male managers have a greater impact on sales than women, but this impact is very low. *Meetings.colleagues* variable (0.06) implies that, if there are more meetings with colleagues in the same economic sector to discuss and implement marketing strategies, there will be an increase in sales but, they will have little impact. *Network.business* variable (-0.05), when sales increase, it is less necessary for the company to belong to associations.

This study showed that the three hypotheses defined in the study were demonstrated, according to the degree of significance of the variables (see Table 3).

Table 3. Hypothesis supported

Hypothesis	Definition	Supported
H ₁	Human capital as a generator and distributor of knowledge increases the capacity for innovation and competitiveness of the company.	Yes
H ₂	From the relationships of managers and salespeople with the environment, knowledge can be created and managed to impact the growth in sales	Yes
H ₃	The processes, activities and strategies of the marketing area improve and increase sales when knowledge is managed.	Yes

FUTURE RESEARCH DIRECTIONS

Future studies may consider the use of objective indicators, to further evaluate the hypotheses that were proposed. They could also try to evaluate other mediators in the relationship between the KM and the growth in sales. This study tested hypotheses with a survey that only provided cross-sectional data. Future studies may include obtaining longitudinal data, to observe changes throughout the process when implementing a strategic KM model. Another line of future research could be to validate the proposed model in a real environment of an organizational unit of a real SME.

CONCLUSION

The results indicate that the price and seller's turnover variables are the ones that have a greater relationship with sales. It can also be deduced that managing knowledge significantly influences the marketing area of companies and therefore, it influences the growth in sales. The research explains that the 56% of the variables under study have a significant relationship with sales, showing that the management initiative in human capital investment (salespeople and other marketing personnel) in a company promotes the growth of sales. The lack of initiative from both, management personnel and sellers, affects the marketing strategies and therefore the sales. The variables related to KM in the activities of the management, as well as in the activities of the sellers generate innovation and competitiveness. However, acquiring knowledge to correctly select and apply marketing strategies (relational capital) influences the 67% of sales.

The following relationship could be established as:

Sales + Organizational Learning Capacity = Human Capital + Relational Capital + Structural Capital

Human capital includes ideas, initiative, manager and seller's activities. Relational capital includes feedback and knowledge creation between manager and sellers. Structural capital includes relations with the environment to increase marketing strategies.

It could be inferred that most managers prefer written and physically filed documentation, due to the lack of knowledge of the use of ICT. Being unaware that the use of these strategies could help an organization to expand its range of knowledge and to increase the speed of knowledge transfer.

The results of this study have some limitations, and some points need further research. First, this study focuses on the activities and processes of the manager and the sellers as generators of knowledge, without examining the activities concerning customers and suppliers, which may be the subject of future research studies. Second, the relationships between the variables in this study are valuable for further study in other contexts. Third, this study employs subjective measures of the interviewed staff, managers, making their subjective assessments may differ from the objective data.

This paper evaluates activities related to the intellectual capital of the marketing area of a company and the interactive relationships between its different dimensions: human capital, relational capital and structural capital. Providing KM managers with a theoretical model that demonstrates the relevance of organizational learning in innovation and competitiveness, generating an increase in sales. This study also allows managers to assess the strength and weakness of the intellectual capacity of their company, and to determine if it is necessary to invest or not in it.

KEY TERMS AND DEFINITIONS

Explicit Knowledge: It is the knowledge that can be readily articulated, codified, stored, and accessed. It can be easily transmitted to others.

Intellectual Capital: Sum of human capital, structural capital, and relational capital. It is any factor that contributes to the value generating processes of the company.

Knowledge Management: It is about getting the right knowledge to the right person at the right time. It implies a strong tie to corporate strategy, understanding from where and in which types knowledge could be found, in order to create processes that span organizational functions.

Marketing: The promoting and selling of products or services.

Organizational Learning: It is a process that enhances its collective ability to accept and respond to internal and external change.

Sales: The exchange of something for money.

Small and Medium Enterprise: It is a business or company where there are less than 250 employees; and which has an annual turnover not exceeding 50 million euro.

Tacit Knowledge: It is the knowledge that is difficult to transfer to another person by means of writing it down or verbalizing it.

A Theoretical Approach Exploring Knowledge Transmission Across Generations in Family SMEs

Filippo Ferrari

University of Bologna, Italy

INTRODUCTION

Although family business is a well-developed field of research, scholars are not unanimous in defining a family firm. This chapter follows Chua et al. (1999, p25), by defining a family business as: “a business governed and/or managed with the intention to shape and pursue the vision of the business held by a dominant coalition controlled by members of the same family or a small number of families in a manner that is *potentially sustainable across generations* of the family or families” (italics added for emphasis).

However, regarding such sustainability, family firms show a long-term survival problem: approximately 40% make a positive transition to the second generation and only 12% to the third (Bridge et al., 2003). De Massis et al (2008), in their review, summarized the main causes preventing intra-family succession, identifying individual, relational, contextual, financial and even process factors. Thus business transmission seems, without doubt, to be the most critical event in a family firm’s life. This event is a process, rather than a moment: the founder slowly hands over the management of the business to the successor, who gradually becomes an entrepreneur (Chirico, 2008). Transferring, sharing and creating knowledge between people who are involved in succession plays a fundamental role in this delicate and uncertain process (Cabrera-Suarez, 2001; Cope, 2005; Koiranen, Chirico, 2006; Le Breton-Miller, 2004), but this knowledge transfer does not occur automatically (Boyd et al. 2015; Del Giudice, 2011; Konopaski et al., 2015). Indeed, an important reason for the failure of organizational processes to facilitate knowledge sharing is the lack of consideration for how the organizational and interpersonal context influences knowledge sharing (Carter & Scarbrough, 2001; Voelpel, Dous, & Davenport, 2005). Organizational Learning Theories applied to family business (Moore, 2009) assert that knowledge is a fundamental asset in ensuring a firm’s development and survival (Durst & Edvardsson, 2012; Grant, 1996; for a review see Wang & Noe, 2010). However, although business transmission is maybe the most investigated issue by family business scholars, to date the process through which knowledge is created, shared and transferred across generations has not been comprehensively examined (Chirico, 2008). A little research has focused on specific factors (e.g. leadership style: Cunningham et al., 2016), but current research is far from being completed. Therefore, the main purpose of this chapter is to suggest a theoretical framework for addressing investigation of family firm heterogeneity in knowledge sharing.

Literature suggests that succession is largely in the control of the incumbent leader of the family firm (Lansberg, 1988; Malone, 1989; Rubenson & Gupta, 1996) and in SMEs in particular seniors, (often tacitly), share their knowledge and expertise with juniors day-by-day. Although literature acknowledges the relevance of knowledge sharing to organizational performance (for a review see Wang & Noe, 2010), research shows that one of the main causes, that occurs recursively, of firm failure is the successor’s

DOI: 10.4018/978-1-7998-3473-1.ch105

business incompetence (Carter, Van Auken, 2006; Gibb, Webb, 1980), thus suggesting that knowledge is not always properly transferred between generations. In particular, current literature has not until now fully investigated individual and organizational factors which affect knowledge sharing during business transmission, both formally and tacitly. Hence, drawing on Organizational Learning Theories (Argote, 1999; Kogut & Zander, 1992, 1996; Spender, 1996), this chapter highlights how knowledge sharing and transferring processes should be not properly implemented during business transmission.

Structural, (i.e. permanent and ongoing), processes aimed at sharing and managing organizational knowledge are however not enough to ensure successor's business competence. In this sense planned and specific training processes play a fundamental role in junior's firm-specific skills development, especially if the next generation does not have a 'proper' or well-rounded CV and/or shows a lack of motivation for their (future) entrepreneurial role. Indeed, literature shows that training is a key component in leadership development (e.g. Collins & Holton, 2004), and another factor (that is) integral to corporate success. The organizational process aimed at increasing the available knowledge is not in the control of the incumbent leader exclusively, but also involves the next generation and non-family members. Literature (Lave, 1993; Gherardi & Nicolini, 2004) suggests that the 'peripheral legitimated participation' of the junior ensures the best outcomes in terms of knowledge sharing and development, due to the Situated Learning process (Boyd et al. 2015; Hamilton, 2011; Lave, 1993). From this point of view, it is maybe more appropriate to consider the next generation's skill development as a learning rather than a training process. SMEs usually present informal training processes (Cardon, Stevens, 2004), hence for overcoming the limitations of the traditional on-the-job-training, (poor methodology, lack of strategic vision), it is necessary that the next generation plays an active role in developing entrepreneurial skills. However, little research (Murphy, Lambrechts, 2015; Stavrou, 1999) has investigated the role played by the offspring during the business transmission process until now. Thus, learning and training processes should be properly implemented and carried out actively by the involved generations, also with the involvement of non-family members. However, drawing on a situated learning approach to knowledge sharing and development, this chapter highlights both organizational and individual factors undermining next generation's skills development.

THEORETICAL BACKGROUND

In the field of organizational literature, *knowledge* is defined as information processed by individuals including ideas, facts, expertise, and judgements relevant for individual, team, and organizational performance (e.g., Alavi & Leidner, 2001; Bartol & Srivastava, 2002; Durst & Edvardsson, 2012). For instance, Alavi & Leiner define knowledge as "information possessed in the mind of individuals (2001, 109). *Knowledge sharing* refers to the provision of task information and know-how to help others and to collaborate with others to solve problems, develop new ideas, or implement policies or procedures (Cummings, 2004; Pulakos, Dorsey, & Borman, 2003). Family Capital Theory (Moore, 2009; Hoffman et al., 2006; Danes et al., 2009), and the Knowledge-Based View (Càbrera-Suarez et al., 2001; Hatak, Roessl, 2015) offer copious suggestions regarding how to share and transmit firm-specific knowledge in organizations. Both approaches provide useful insights into assessing and explaining strengths and weaknesses of the knowledge sharing process, and are very suitable for investigating business transmission processes. In this sense, in the context of family firms, succession planning refers to the deliberate and formal process that facilitates the transfer of management control from one family member to another (Sharma, 1997). However in order to ensure a positive outcome of business transmission, succession planning should provide indications of the specific knowledge and expertise areas which should be transferred

to the next generation. Furthermore, transferring knowledge internally sets the basis for innovating and improving efficiency, thus realizing the potential value of that knowledge (Davenport & Prusak, 1998).

Regarding this knowledge sharing process, small family firms seem to be in a favourable position, due to their (small) size and strong everyday relationships among family members. Bjuggren et al. (2001) point out that there is a form of idiosyncratic family knowledge (and loyalty), that makes intergenerational succession within the family more profitable than other types of succession. Repeated (and frequent) interactions make the development of bilateral knowledge transfer easier and it is intensified through “close-knit groups” whose members identify themselves with a larger collective (Kogut & Zander, 1992), therefore knowledge transfer is favoured in family firms (Sirmon & Hitt, 2003). However, in spite of this favourable situation, statistics show (Cabrera-Suarez, 2001; Koironen, Chirico, 2006; Le Breton-Miller, 2004) that next generation failure could be explained by the scarce knowledge and skill levels of the successor. In particular, the involved generations’ lack of capacity and/or willingness to create, share, transfer and acquire the appropriate ‘knowledge’ from generation to generation (Szulanski, 1996; Kellermanns & Eddleston., 2004). Therefore catastrophic statistics in business transmission failure lead researchers to take a pessimistic stance, and force them to try to investigate if organizational knowledge is really shared in business transmission and/or transmitted to the next generation.

An important reason for the failure of knowledge sharing is the lack of consideration for how the organizational and interpersonal context as well as individual characteristics influence knowledge sharing (Carter & Scarbrough, 2001; Voelpel, Dous, & Davenport, 2005). In the same way, Cunningham et al. (2016; 2017) suggested that knowledge sharing is not something that happens organically, but instead relies on careful leadership approaches in order to foster a culture of sharing and training (Srivastava, Bartol, & Locke, 2006).

Other authors suggest one major inhibitor of knowledge sharing is that knowledge can be considered a source of power and superiority (e.g., Gupta & Govindarajan, 2000; Kim & Mauborgne, 1998; Szulanski, 1996), and this fact could trigger conflicts/rivalries in senior-junior relationships (Lansberg, 1988; De Massis et al., 2008), in turn boycotting the next generation’s skills development. Similarly, due to the fact that Chrisman et al. (1998) and Sharma and Rao (2000) both found that family firms consider integrity to be the most important attribute of a potential successor, a lack of trust in the successors could undermine knowledge transmission.

Finally, having a clear transitional role for both the incumbent and the successor is vital (De Massis et al., 2008; Lansberg, 1988; Le Breton-Miller et al., 2004; Sharma et al., 2001). Thus, not clearly defining the roles of the incumbent and the potential successor(s) is another well-known cause of failures in business transmission.

In summary, current research addresses the issue of heterogeneity in small family firms in terms of a knowledge sharing approach. However empirical research providing an explanation for such SME specific features is still scarce. Due to ambiguous available evidence, and the current lack of research, setting up a theoretical framework for collecting empirical data about knowledge sharing in family business becomes an urgent requirement in order to shed light on organizational factors undermining business transmission success. Hence it is possible to formalize the first theoretical proposition:

P1: In family firms, specific factors affect organizational knowledge sharing and transmission during business succession.

Although both belong to the organizational learning field of research, knowledge sharing and management and training processes are theoretically different. Before being shared and transmitted, organizational knowledge should be created and made explicit. Furthermore, training processes follow and support knowledge sharing processes (and vice versa), but remain separate. At its most basic level, training can

be thought of as “the planned activities designed to promote the acquisition of knowledge (i.e., need to know), skills (i.e., need to do), and attitudes (i.e., need to feel)” (Salas et al., 2012, 77). The small size typical of SMEs does not in itself guarantee the activation of planned training paths for juniors, who could experience frustration and exclusion dynamics in their professional growth. For instance, in spite of the relevance of knowledge sharing and training processes, sometimes family members find difficulty in informally transmitting knowledge, even purposefully centralizing such knowledge in one or a few individuals (Cabrera-Suarez et al., 2001; Zahra et al., 2007), typically the founder. In a small business, the entrepreneur does not often have time (or even the skills) to train the next generation, who therefore must play an active part in the process of acquiring organizational knowledge (themselves). Moreover, current literature suggests that SMEs scarcely use formalized training practices, due to their size and lack of sufficient economic resources to invest in the development of human resources (Cardon, Stevens, 2004). Furthermore, seniors with a high level of performance goal orientation may feel that training depletes the time and effort available for other work activities that can result in greater personal benefits and rewards by exceeding expectations on performance goals (Szulanski, 1996). Additionally, the available empirical evidence (Ferrari, 2017; 2019; 2019a) suggests that often the juniors, (the daughters especially), do not have a technically adequate CV, and this could be an additional obstacle to their training participation.

This scenario suggests that, in order to investigate training and learning processes in SMEs, it is advisable to apply theoretical models that emphasize the on-the-job transmission of tacit and firm-specific knowledge in particular. As a consequence, a Situated Learning approach seems to be better suited to investigating if and how the next generation play a strategic role in developing their entrepreneurial skills and knowledge (Hamilton, 2011).

Literature emphasizes that not only knowledge sharing, but every learning process including the development of professional skills is a social process (Boyd et al. 2015). It is the specific dynamics of the group that help to define these skills and apply them to the organizational context. This approach is rooted in cultural psychology (Vigotskji, 1990), and continues to provide a fundamental model of design and intervention in organizational contexts. More recently, the theoretical roots are from the field of Situated Learning (Boyd et al. 2015; Hamilton, 2011; Lave, 1993; Lave, Wenger, 2005), which identifies the so called Peripheral Legitimate Participation as a way to develop the junior’s skills in a specific organizational context. It is the junior’s active participation in a community of practice (i.e. a formal/informal enduring group sharing interests, practices, values: Lave, Wenger, 1991), made up of family and non-family members, that fosters knowledge sharing and the improvement of contextual skills. Given this theoretical scenario, it is now possible to formalize the second theoretical proposition:

P2: In family firms, specific factors affect the next generation’s training/learning process during business succession.

Figure 1 provides a breakdown of the structure of the theoretical framework drawn on current literature.

THEORETICAL DEVELOPMENT

The first proposition suggests that in a sample of SMEs, the knowledge sharing and transmission process could show some weaknesses and evoke some criticism. Available family business literature (e.g. Koiranen, Chirico, 2006; Kellermanns et al., 2004; Le Breton-Miller, 2004; Szulanski, 1996) highlights many factors could undermine knowledge sharing and transmission:

Figure 1. Theoretical model - Key aspects in organizational learning processes during business succession
Source: Author's own construct

- lack of planned formal/structural knowledge sharing processes (Cabrera-Suarez, 2001; De Massis et al., 2008).
- conflicts/rivalries/competition in parent-child relationships (Sharma et al., 2001; Sveen & Lank, 1993; Venter et al., 2005).
- hazards/risks associated with the strong need for consensus among family members or to a lack of successor (s)'s legitimization (Schein, 1983; Walsh, 1994; Ward, 1988).
- lack of clear role definition of the incumbent and potential successor(s) (Le Breton-Miller et al., 2004; Organ, 1990; Rosenberg, 1991).

Therefore, drawing on existent literature (for a review, see De Massis et al., 2008, Ferrari, 2017), investigation process should consider several attention points, as suggested by Table 1.

Table 1. Intergenerational knowledge sharing and transmission – Synoptic representation of organizational features and related attention points

Investigated features	Attention points
Existing formal/structural knowledge sharing processes	• Official knowledge management procedures usually don't exist, knowledge sharing happens/occurs during everyday discussions and informal meetings. • This different approach makes effective knowledge sharing difficult
Conflicts/rivalries/competition in parent-child relationships	Knowledge is a power source in intergenerational turnover
Hazards associated with the strong need for consensus among family members or to a lack of successor (s)'s legitimization	• High level of centralization in decision process • Juniors show great difficulty in being legitimated in stakeholders' opinion, and consequently to access to external knowledge • Seniors manage directly (without substantial delegation) the relationships with the most important stakeholders
Lack of clear role definition of the incumbent and the potential successor(s)	• The distance (especially physical, but also 'logical' and hierarchical) between a senior's and a son/daughter's job is almost always notable. • Senior and Junior usually carry out different jobs substantially • Ample junior autonomy in carrying out his/her job, but not in decision-making

Source: Author's own construct

Available family business literature (Del Giudice, 2011; De Massis, 2008; Konopaski et al., 2015) highlights knowledge sharing is usually poor within family firms. The distance (especially physical, but also 'logical' and hierarchical) between a senior's and a son/daughter's job is often consistently notable. Usually juniors perform their job in a different sector or function/role as the founder. No daughter does the same job as the founder, even when the founder is the mother (Ferrari, 2017; 2019a). Juniors face considerable difficulty in introducing innovation, especially in process rather than in product. Re-organizations and new management methods are systematically hindered by the seniors. Finally, seniors look after the most important clients and providers directly, showing low delegation orientation, with the exception of the daily routines. In summary, the lack of an adequate knowledge sharing process to bridge the gap in technical skills of the next generations is the basis of a paradoxical system. Juniors usually show total autonomy but not in decision-making, they don't have the opportunity to change the current situation, especially with regard to organizational procedures. Next generations often have more managerial skills, they attend courses willingly, but they have great difficulty in applying what they have learned to the job. Knowledge sharing therefore faces a double obstacle: seniors don't share their experience, and juniors are not able to transfer their managerial skills to the job. These results suggest situation involving family firms are in contrast to what is described in the literature on organizational learning, and could help at least partially explain why, in most cases, the family firm does not survive the one who founded it.

The second proposition suggests that in SMEs, also the training/learning process could show some weaknesses and evoke some criticism. Available family business literature highlights many factors could undermine such participation;

- conflicts between incumbent/potential successor(s) and non-family members such as lack of trust (Cespedes and Galford, 2004).
- lack of commitment to the potential successor(s) by non-family members (Cespedes & Galford, 2004; Kets de Vries, 1986).

- late or insufficient exposure of the potential successor(s) to the business (Cabrera-Suárez et al., 2001).
- not giving the potential successor(s) sufficient feedback about the succession progress and incorrectly evaluating the gaps between the potential successor's needs and abilities (Le Breton-Miller et al., 2004).

Therefore, drawing on existent family business literature (for a review, see De Massis et al., 2008; Ferrari, 2017), investigation process should consider several attention points, as suggested by Table 2.

Table 2. Training/learning process involving the next generation – Synoptic representation of organizational features and related attention points

Investigated features	Attention points
Conflicts between incumbent/potential successor(s) and non-family members (e.g. lack of trust)	• The junior perceived him./herself as 'the son/daughter of...' • In order to appear fair, the seniors often treat the juniors more strictly than non-family members • On-the-job training is often provided by non-family members
Lack of trust in the potential successor(s)	Senior shows a lack of trust in successor's entrepreneurial rather than managerial attitude, especially when the junior is the daughter.
Failure to train potential successor(s)	• Junior training is consistent with senior experience: nevertheless, it doesn't transmit core competencies • In the founders' opinion, the daughters almost always present a lack of entrepreneurial attitude and skills, nevertheless training is not provided.
Late or insufficient exposure of the potential successor(s) to the business;	• University background and early experiences are the basis of the male juniors' activities. • The daughters show a skill mismatch due to their educational path • The daughters usually join the family firm later, after job experiences in a different sector
Lack of next generation's career planning	'Blind career'; career steps as makeshift solution
Not giving the potential successor(s) sufficient feedback about the succession progress.	A feeling of frustration often arises among the second generation, due to the fact that they attended university, thus their theoretical background is more up-to-date.
Incorrectly evaluation of the gaps between the potential successor's needs and abilities	The sample consider their current job consistent with the type of university course they attended, but with notable differences between males and females

Source: Author's own construct

In spite of the small dimensions of the firms, both training and learning processes seem to fail in supporting knowledge sharing between generations. Literature suggests the first generations of entrepreneurs are strongly focused on the business, and their children seem quite disheartened and confused, and often with a distinct lack of future orientation. The entrepreneurs do not help their children to become the future bosses: the prominent idea seems to be that the son or the daughter must grow up autonomously, inside the family firm of course, but without formal training or a defined/relevant career path - just like their father/mother did when they founded their own firm.

In particular, literature suggests (Hamilton, 2011) in family firms the peripheral legitimated participation is often hindered. For example, Boyd et al. (2015) highlight that a certain "transactional atmosphere" (family cohesiveness, commitment, traditions and underlying values) is needed so that the knowledge

transfer is realized. Often, juniors are perceived as doubtful by seniors, while they would instead like to feel appreciated and valued. The junior's attention to managerial aspects like finance and accounting is often not appreciated by the senior, who complains about their children's scarce entrepreneurial attitude and low risk-orientation instead. Juniors feel constantly under examination, they have difficulties in the legitimization process and the senior does not help them, because they do not want to create suspected favoritism.

Literature suggests there is a lack of managerialisation in family firms (Ward, 1987; 2004): in these firms everything seems to happen spontaneously, without guidance. SMEs should counterbalance the lack of this managerialisation with the physical sharing of work-spaces, and thus encourage knowledge sharing. However, this counterbalancing often does not happen.

In brief, the overall evidence shows firms which are scarcely future-oriented, and this lack of strategy affects the training policies negatively. Empirical data shows strong limitations in the knowledge sharing process between generations involved in business transmission. The founders do not share and/or discuss (or share very little of) the strategic decisions with their children. Finally, and maybe more prominent, the second generation (in particular the daughters) show a low level of skills, especially in the core business of the firm, and especially if this core business operates in a technical sector, such as mechanics or electronics. Daughters often show a mismatch between carried out educational path and current job. Training/learning strategies do not help the transmission of strategic knowledge between generations in order to fill this skill gap.

DISCUSSION

A theoretical framework should also explain a phenomenon 'from the inside', rather than statistically describe it (Norqvist et al. 2009). Therefore, in order to discuss the results, it is necessary to move from the 'How' of the organizational learning process to the 'Why'. This chapter suggests that seniors pay little attention to the knowledge sharing process during business transmission. Furthermore, the next generation does not play an active role in searching for knowledge, legitimising itself and more in general shows a lack of 'strategic thought'. This could be due to both personal characteristics of the involved generation (e.g. see Schlepphorst, Moog, 2014) and contextual/environmental influence (e.g. see Overbeck et al., 2015). Regarding the former, cognitive and personality factors should be considered, such as successors' skill mismatch and seniors' abandon resistance. Regarding the latter, cultural factors (for example, gender stereotypes and social expectations) can affect future orientation which, in turn, affects every strategic organizational training and learning decision .

Dispositional Factors: Skill Mismatch and Abandon Resistance

Incorrectly evaluating the gaps between needs and potential successor's abilities and failing to train potential successor(s) (Fischetti, 1997; Fleming, 2000; Le Breton-Miller et al., 2004) are negative factors well-known by scholars. Literature suggests this fact could be due to the different jobs carried out by the involved generations, and could result in a skill shortage and/or skill mismatch between skills required by the entrepreneurial job and skills possessed by the next generation. Furthermore, seeing as the distance (especially physical, but also 'logical' and hierarchical) between a senior's and a son/daughter's job is almost always notable, this could undermine knowledge sharing, especially 'tacit knowledge' (Chirico, 2008; Cabrera-Suarez, 2001; Chirico, Salvato, 2008) related to everyday experiences and grounded on

practical skills rather than theoretical ones. Due to its nature, tacit knowledge could not be formally taught to the next generation, but it should be shared with them (Nonaka, 1991). Therefore, the next generations' careers should be carried out side-by-side with the first generation, in order to develop entrepreneurial and managerial skills. If this does not happen, second generations' careers could easily result in a skill shortage/mismatch. Cunningham and colleagues (2017) show that a perceived shared and common organizational environment is a pre-requisite for triggering a knowledge sharing process. Thus, job mismatch could be the cause of poor investment in training due to a vicious circle: different carried out jobs hinder knowledge sharing, which increases the distance (both real and perceived) between the possessed skills. This difference in turn leads to further differentiation of the jobs and so on ... The case of daughters is suggestive, of when the job is often designed, (or maybe even invented) from scratch, due to their CV/skill gap (Ferrari, 2017).

The available empirical evidence (Cadieux et al., 2002; Vera, Dean, 2005) shows the seniors' extreme reluctance in leaving their job to their children, even once they retire (Cadieux et al., 2002). Literature also suggests a strong abandon resistance shown by the senior, which results in a procrastination of the knowledge sharing process. The consequence of this reluctance is an incomplete succession (i.e., the founding or succeeded generation retains a significant role in the organization post-succession). Some authors (Davis, Harveston, 1999) called this situation the *founder's shadow*, defining it as "a prior generation's excessive and inappropriate involvement in an organization, possibly causing social disruption in the organization" (Davis, Harveston, 1999, 311; see also Harvey, Evans, 1995).

Several authors (Barnes, Hershon, 1976; Kets de Vries, 1977, 1993; Lansberg, 1988; Peay, Dyer, 1989; Rubenson, Gupta, 1996) confirm that some sources of resistance to business transmission could originate from characteristics of the entrepreneur. For instance, the founders' will to retire is perhaps the most important feature in order to ensure a positive outcome of business transmission (Doud, 1999, Mazza, 2001). A long and undetermined waiting period before taking over the job from a parent, could likely result in a successor's loss of interest in the business (Stavrou, 1999). Such resistance, and the consequent lack of knowledge sharing, can be explained by psychological motivations: the fear of the loss of power and the denial of the approximation of the biological end of life (Ferrari, 2005; Scabini, Iafrate, 2003).

In summary, research has previously focused on the cognitive attributes of the next generation of entrepreneurs suggesting that often the successor is 'left in the dark' (Schlepphorst, Moog, 2014), without guidance and without an explicit understanding of job requirements and family expectations. This situation seems widespread also among family SMEs and more severe when involving the daughter.

Contextual Factors: Gender Stereotypes and Social Expectations

Beyond a cognitive explanation, cross-cultural studies show differences in facing business succession depending on the specific culture (Gupta, Levenburg, 2010). Following this stream of research, a number of studies (for example, Tàpies, Navarra, 2010; Thomas and Mueller, 2000; Valdez, Richardson, 2013; Welsh, Raven, 2006) have explored the connection between contextual characteristics and entrepreneurial activity. For instance, empirical evidence suggests that business transmission processes face major criticism when a daughter is involved (Dumas, 1989, 1990, 1992; Curimbaba, 2002; Ferrari, 2015; 2017; Lozano et al., 2011; Vera and Dean, 2005).

The companies invest little in their daughters, as they will be the business owners but not the CEOs, because they do not have the appropriate technical background: they will have to hire external managers or the company will be sold. However, of course, the daughters have no proper training because their

school choices are the result of gender stereotypes, as well as their career. As a result, in family firms there is a dearth of daughter successors (Overbeck et al., 2013).

This female successor shortage could be due to the complexity of gender norms and vision that could even lead to covert sexism. Sexism refers to discriminatory practices (against a particular gender), including overt and nuanced or subtle forms of sexism (Benokraitis and Feagin, 1986; Benokraitis, 1997; Jandeska and Kraimer, 2005). Covert sexism influences education, politics, religion, law, and other environmental factors (Benokraitis, 1997) that may influence daughter succession (Overbeck et al., 2015). Covert sexism could easily result in ‘daughter’s invisibility’ as successor, or gender stereotypes in job assignment. Many women in non-traditional jobs find themselves being ignored, without role models, or excluded from discussions and/or training activities (Benokraitis, 1997), and this seems to be the case of several of daughters.

In addition, social expectations regarding the entrepreneur and his social identity, (i.e. the categorization of oneself as a member of a group: Tajfel, Turner, 1986; Ferrari, 2014; De Massis, 2012), after retirement play an important role in explaining resistance to abandon. Thus, it is also possible that the entrepreneur is unaware of the problem, due to institutional normative pressure. This fact could have historical motivations. In its history, Italy has always been characterized by elderly males dominating all the key positions: to desert a top position means to desert the only source of social legitimization. Hence emerges, at a normative level, a sort of imposition in defending the possessed position. From the entrepreneurs’ point of view, passing the torch is perceived as the same as passing away. As reported by a son (Ferrari, 2015a): ‘When we argue about a future, hypothetical business transmission, my father (an 83 year old grandfather) always says: ‘I’m still not ready for the playground with my grandchildren...!’

CONCLUSION

The deductive insights suggested by this chapter can be finally presented according to suggestions drawn from the above mentioned organizational literature. This helps to better clarify the relevance of this framework, both for theory and practice and to go beyond the theoretical nature of this study. In particular, it’s possible to identify several critical areas in knowledge transmission and sharing process, which are summarized as follows and could undermine organizational performance.

Business Transmission Process

Research shows that one of the main causes of firm failure occurring recursively is the successor’s business incompetence (Carter, Van Auken, 2006; Gibb, Webb, 1980). Furthermore, statistics show (Cabrera-Suarez, 2001; Koiranen, Chirico, 2006; Le Breton-Miller, 2004) that second generation failure could be explained by the scarce will/desire to or skills of the involved generation in sharing knowledge and transmitting it from one generation to another. Given this widespread evidence in literature, the failures in knowledge sharing described in this chapter could lead to negative outcomes of process transmission, due to the successor’s business incompetence.

Organizational Reliability and Resilience

Literature shows that, even in SMEs, the founders often work independently from their children. Consequently, both develop significant knowledge, routines, and experience severally, that increase the likeli-

hood of solutions being found quickly and at reasonable costs. This fact, of course, is an organizational strength because it leads to maximum efficiency and skills development; but could also lead the founders to become indispensable, and the cost (both psychological and economical) of their replacement increases. Furthermore, a problem of reliability arises, due to this fact that the founder is irreplaceable. Consistent with High Reliability Organizations Theory (Weick, 1995; Weick, Sutcliffe, 2007), failures in knowledge sharing could lead to a firm's unreliability due to negative effects of unexpected external shocks like the death or severe illness of the founder.

Knowledge Sharing Process Based on Systemic Approach

The relative isolation of the seniors in their activities and the difficulties experienced by juniors in legitimate peripheral participation testify to the solitude of the next generation in enriching the process of creating and transmitting knowledge. Therefore it becomes necessary (Ferrari, 2005, Scabini, Iafrate, 2003) to make it clear to the involved generations that the ability to cope with the transmission process arises from the collective ability to see the resources available, to organize and use them for the purposes desired. Resources/knowledge must be considered not as possessing an objective good or personal data of members, but as a result of the organizational ability of the family.

Development of a Future-Oriented Family System

Literature shows a strong resistance to abandonment by the senior: this fact jeopardizes the probability of survival of the firm itself (Piantoni, 1990). Thus, the last but perhaps most difficult goal in a business transmission process is to make the founder aware of the fact that, from a psychological point of view, the second generation are grateful for their inheritance of the business only with a future-oriented view (Scabini, Iafrate, 2003). The successors, striving autonomously for the future survival of the firm, acknowledge the value of the inherited firm, and will also eventually acknowledge the worth/value of the previous generation's work. Removing the founder, and taking care of the firm, is the successor's only way to say 'Thank you'.

FUTURE RESEARCH DIRECTIONS

The here presented model has several future implications for organizational learning field of research, from a methodological point of view mainly. For instance, in order to go beyond theoretical position and apply this theoretical model to empirical research, a qualitative protocol is advisable: this kind approach is relevant for describing and/or explaining social phenomena "from the inside" (Gibbs, 2007), providing a rich and in-depth examination of the organizational context in which knowledge sharing occurs. The choice of this methodological option is due to the fact that available literature reviews highlight that quantitative research about knowledge sharing suffer from several significant limitations (Wang, Noe, 2010). Firstly, the majority of studies measured knowledge sharing using either willingness (or intention) to share knowledge or self-reported knowledge sharing behaviours. In addition, several measures combined knowledge sharing with utilizing knowledge and/or seeking knowledge (e.g., Cabrera et al., 2006; Lee et al., 2006). Secondly, all variables were based on a questionnaire completed by a single source in one time period. Furthermore, a qualitative approach is advisable because the research addresses 'sensitive' issues, which are not very suitable for quantification, and searches for the meanings that lie behind

actions focusing on understanding rather than measuring (Nordqvist, Hall, & Melin, 2009; Silverman, 2010). Moreover, while on one hand it's relatively easy to collect data about best practices, it seems very difficult to obtain data about failures (e.g. psychological barriers like 'jealousy', tacit competition, sabotage etc.) in knowledge sharing within the family, and often the elicited responses are biased, if not explicitly denied. For all these reasons, this theoretical model suggests to use a qualitative protocol, collecting interview data that would otherwise have been difficult to obtain through other means, such as questionnaires (Astrachan, Jaskiewicz, 2008; Zellweger, Astrachan, 2008).

Finally, as suggested by De Massis and colleagues (2008, 193) "an approach to solve the access problem would be to collect data from or through family business consultants". Thus, in order to overcome resistance and collect comparable data, data should be gathered (for instance) by a consultant during an ample multi-firm institutional project.

The limitations of this model should be considered, and overcome by future research. Although theoretically, this chapter suggests that Organizational Learning Theories and Family Capital Theory do not show a good fit in explaining the dynamics of family firm knowledge sharing in all national contexts. In the developing economies of Asia and Africa as well as the developed ones in North America, Europe, Australia, and New Zealand there is little case study research in the existing literature on cross-cultural gender issues in family firm ownership and succession (Halkias et al., 2008; 2010). The notion of a "country institutional profile" was introduced by Kostova (1997). This profile must be directed towards a specific sphere of activity or field and cannot be generalized across multiple domains (Busenitz et al., 2000). Thus, future research could provide a contribution in order to understand business transmission in specific national context from an institutional point of view, answering the following question: 'Do geographical, cultural and even religious factors affect the strategic decisions about business succession and the related managerial practices, like knowledge management? '

KEY TERMS AND DEFINITIONS

Community of Practice: A formal/informal enduring group sharing interests, practices, values.

Knowledge Sharing: In the field of organizational literature, knowledge sharing refers to the provision of task information and know-how to help others and to collaborate with others to solve problems, develop new ideas, or implement policies or procedures.

Peripheral Legitimated Participation: Describes how newcomers become experienced members and eventually old timers of a community of practice or collaborative project. LPP identifies learning as a contextual social phenomenon, achieved through participation in a community practice

Situated Learning: Situated learning is a theory on how individuals acquire professional skills, extending research on apprenticeship into how legitimate peripheral participation leads to membership in a community of practice.

Industry 4.0:

A Strategy of the European Union and Germany to Promote the Manufacturing Industries – Opportunities and Challenges of Digitization

Immo H. Wernicke

German Government (Retired), Germany

INTRODUCTION

The German Government and the European Commission have launched the strategic initiative named Industrie 4.0 for a re-industrialization in Germany and Europe, and for achieving more competitiveness and sustainable growth. The top down strategy promotes the implementation of digital technologies especially at Small and Middle Sized Enterprises (SMEs) of the traditional manufacturing industries (Novakova, D. 2017). Digital technologies include Cyber Physical Systems, Cloud Computing, Robotics, 3D-printer-technology, Smart Factories, Additive-Manufacturing, and Artificial Intelligence. The impact of digitization on the economy, on employment, and on business results of SMEs is not yet clear due to insufficient availability of business data and results of pilot projects on enterprise level. Balasingham, K. (2016) argues in his thesis that Industrie 4.0 is still a very recent topic. The confidentiality of business data is to be taken into account, too.

Thus the methodological framework of a SWOT-Analysis normally used to assess organizations and projects might be most convenient (Investopedia, 2018) to discuss the strength, weakness, challenges, and opportunities of the strategy and the threats on its implementation by SMEs. The contribution is addressed to politicians, academics, media, startups and managers of SMEs that are less familiar with Industrie 4.0.

BACKGROUND

The term Industrie 4.0 is the “name given to the German strategic initiative to establish Germany as a lead market and provider of advanced manufacturing solutions“, explains the German Trade and Invest Association (2018). In 2011, at the German International Fair on Industries in Hanover (2018) the concept Industrie 4.0 and its technologies have been presented to the public by the German Government and by digitally leading enterprises like Bosch and Siemens. The term is also a German “brand” of a digital platform being founded by the Government in collaboration with large enterprises and company associations in 2013 (Banthien, H. 2017).

Then President of the EU Commission (2014, 2017), Claude Juncker, is supporting the strategy by the European version Industry 4.0. To promote the “re-industrialization” the EU Commission (2018) has also launched the Digitizing European Industry Program. After the financial crisis SMEs in industries contributed significantly to economic stability (Du Plessis, C.J. 2017). The Industrie 4.0 - programs

DOI: 10.4018/978-1-7998-3473-1.ch106

are funding public and private research and development (R&D) and investment to boost the digital infrastructure and to strengthen competitiveness and economic growth.

The strategy refers to the vision of Rifkin, J. (2015) a former adviser to the German Chancellor Angela Merkel. Rifkin recommends the promotion of Information and Communications Technology Industries (ICT), digital startups and SMEs for establishing a demand driven intelligent production in smart factories: “By digital innovations and renewable energy a digital industrial revolution is on the way in Germany and Europe”.

THE IMPACT OF THE INDUSTRY 4.0 INITIATIVE

National and International Publications

A review of publications on Industrie 4.0 approves the concept has spread world-wide and influenced other sectors, e.g. health, Logistics 4.0, and Agriculture 4.0. Similar programs have been established in the United States, Japan, China, India, South Korea, Brazil, and in many developing countries by taking into account specific national perspectives (Zhong, R.Y., Xu, X., Klotz, E., Newman, S.T. 2017). Masdefiol, R., del Mar, Ståvmo, F. (2016) have checked the feasibility to implement Industrie 4.0 in Sweden. The academic community is committed to stimulate R&D, conferences, studies, and publications on implementing digital technologies in economic sectors (Gausemeier, J., Klocke, F., 2016).

Balasingham, K. (2016), however, emphasizes in his thesis that the implementation of the new technologies in SMEs “is not discussed excessively”. Most companies and organizations have not yet implemented the new digital technologies. The bulk of publications is still provided by the German Government, the EU Commission, and public research institutes. Academic publications focus on reports and analyzes of official papers on this topic and on technical descriptions of the innovations. (Friedrich-Ebert-Foundation, 2018)

Impact of Digitization on the Economy

The impact of digitization on the economy is controversially disputed. Quantitative information about and from innovative SMEs is poor. Trade unions criticize the expected risks of unemployment caused by the digital transformation and robotics and the substitution of labor force. A positive impact on the economy is proposed by the World Economic Forum surveying managers and their investment plans for digitization (Schwab, K., 2018). The EU Commission (2018) estimates the benefits reach “more than €110 billion of annual revenue for our industry until 2020“. The Boston Consultant Group (2015) estimates a 1% per year contribution to Germany’s GDP (Gross Domestic Product) over ten years and the creation of 390,000 jobs, but “the full digital transformation will take 20 years”. Time and cost savings are proposed in consultancy reports of Deloitte and McKinsey (Nilsen, S., Nyberg, 2016). Experts of Roland Berger (publ. 2016) forecast positive results in general.

All estimates are only based on small samples of surveyed managers planning the digitization of their companies. Approved findings about business results on firm level are poor. Price Waterhouse Consulting (2015) and the German Mechanical Engineering Industry Association (2017), are admitting only 15-20% of German SMEs have implemented digital technologies in industrial manufacturing.

The transformation is still at the beginning, and accountant data are confidential (Nilsen, S., Nyberg, 2016). Before digitization, innovative managers have to conduct company assessments, SWOT-analyses,

Figure 1. SWOT-Analysis on the official concept Industrie 4.0 to support SMEs

Sources: Collected from different articles on the concept Industrie 4.0

feasibility studies and master-plans. The methodological framework of the SWOT-analysis will be applied in this article to analyze the strength, weakness, challenges, and the potential opportunities of Industrie 4.0 and its threats on SMEs (Investopedia, 2018). Figure 1 describes the components of the SWOT-Analysis for the discussion of the strategy Industrie 4.0

STRENGTH, OPPORTUNITIES, WEAKNESS, CHALLENGES, AND THREATS OF INDUSTRIE 4.0

THE STRENGTH OF THE STRATEGY INDUSTRIE 4.0

Public Support for Implementing Industrie 4.0 and for Modernizing The Infrastructure

The strength of the high level strategy Industrie 4.0 is due to the market-oriented funding and the promotion of its implementation. The German Government and the EU Commission have increased public budgets for public procurement to modernize the digital and energetic infrastructure, and to support R&D and innovations. EU Commission President Claude Juncker (2014) and the European Investment Bank (2015) have set up the European Investment Fund for Strategic Investments. The fund will mobilize Euro300bn of public and private investment on “the areas of infrastructure, notably broadband and

energy networks, transport infrastructure in industrial centers, education, research and innovation, and renewable energy and energy efficiency“, (Macary, J.P. 2018, Siemens, 2018). For transforming old industrial sites the EU Commission (2017) provides financial means by the European Structural and Investment Funds worth over €450bn.

The German Internet Platform Industrie 4.0 Promotes the Digitization of SMEs

The German Government has set up a digital Plattform Industrie 4.0 as an internet market place for the promotion of the new High Tec strategy. The Secretary General of the platform Banthien, H. (2017) encourages managers of traditional SMEs to use the platform as a market for negotiations and collaborations with digital startups and technical universities. The internet platform is being operated by business associations, trade unions, technical universities, research institutes, and political organizations. Developers and suppliers of digital technologies like Bosch, Daimler, SAP, Siemens and Thyssen-Krupp take part, too. It is one of the largest networks and has links to the EU Commission and to the G20 countries. The stakeholders of the platform cooperate with the Industrial Internet Consortium (USA), the Alliance Industrie du Futur (France), and with countries like Italy and China for digital standardization issues (Banthien, H. 2017).

For acquiring financial investors a separate internet platform is run by the German Digital Hub Initiative (2018). This internet platform enables private investors and venture capital companies to get into contact with digital Startups and SMEs for matchmaking and for checking business opportunities.

International Fairs and Company Associations Set up Strong Institutional Frames

A further institutional strength is built by the world's largest International Fair on Industries in Hanover. The fair is a strong institutional frame and real market place for suppliers and SMEs. It presents all technologies of Industrie 4.0, e.g. Additive manufacturing, Digital twins, 3D printing, Cloud computing, and Robotics. Managers of SMEs can negotiate with leading enterprises that are offering innovative industrial machinery, manufacturing facilities, products, equipment, software, and services. (International Fair on Industries Hanover, 2018)

An important institutional frame is also built by the German Mechanical Engineering Industry Federation (VDMA) organizing the International Mechanical Engineering Summits (2014, 2017) in Berlin. The association provides information on business models and digital innovations in industrial manufacturing also via the internet for SMEs.

BUSINESS OPPORTUNITIES FOR SMES BY DIGITAL TECHNOLOGIES OF INDUSTRIE 4.0

Cloud Computing, Big Data, Blockchain, and Algorithms

Rifkin's vision of a digital industrial revolution is becoming a new reality in industrial production. Digital technologies have been put on the market and provide business opportunities for SMEs.

Hanover Industry Fair Manager Köckler, J. (2017) emphasizes “The technologies needed for the successful digitalization of industrial production are fully developed and ready to go.” (Figure 2)

Figure 2. Technologies of Industrie 4.0 put on the market for SMEs

Source: International Fair on Industries Hanover (2018, 2019)

A basic technology of Industrie 4.0 is Cloud computing for sharing digital platforms and data exchange. Beal, V. (2018) from the National Institute of Standards and Technology defines Cloud computing as a digital system “for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources”. Cloud computing provides managers the access to applications, software, data storage centers and services also in-house. It also allows a remote information exchange between digital and manufacturing SMEs outside the SMEs’ firewalls via the internet (IBM, 2018). Figure 2 presents the main technologies of Industrie 4.0.

Additive Manufacturing, Digital Twins, 3D-Printer-Technology, and Robotics

A prior opportunity to SMEs is provided by Additive Manufacturing, being defined as an innovative digital engineering process applicable in manufacturing (Anderl, R., and Fleischer, J., 2017). This technology is based on Computer Aided Manufacturing (CAM) providing graphical data for the creation of digital twins. Digital twins are linking digital and physical 3D Computer Aided Design (CAD) models. The digital models are virtual representations of physical machines, products, production facilities and of logistics warehouses. They represent all the properties and functions of the planned real entities being equipped with sensor systems. Manufacturers are enabled to a real time combination of digital designing and the modeling of single physical products or complete production facilities. Companies are enabled to optimize the function of machinery, equipment, products and processes.

3D-Printer-Technology for a Decentralized Production

Additive Manufacturing can be connected with the 3D-printer-technology for a customer and demand driven production. 3D printers brought to the market are ready for printing a broad scope of physical products also in size, such as dishes, toys, textiles, and multimedia sets (International Fair on Industries in Hanover, 2018). Users can meanwhile apply all types of pulverized solid materials, including metals, and biomass.

The International Energy Agency (2018) point out the main advantages of 3D printing besides energy and resource savings “reduction of scrap materials, lower inventory costs, less manufacturing complexity, reduced floor space and the ability to deliver manufactured pieces with complex shapes and geometries.” Startups and traditional SMEs can benefit from these customer oriented and cost saving technologies for setting up smart decentralized production sites.

Robotics

Robotics deals with the design, construction, operation, and application of robots and computer systems. The International Organization for Standardization (2018) defines an industrial robot as an “automatically controlled, reprogrammable multipurpose manipulator programmable in three or more axes, which can be either fixed in place or mobile for use in industrial automation applications”. Robots are automated machines that can substitute labor force in the manufacturing process and in dangerous environment. Industrial robots support the production process by handling, forging, metal casting, palletizing, picking, and packaging of products of different sizes. (International Federation of Robotics, 2016). Figure 3 presents a robot as a main component of Industrie 4.0

Figure 3. Will robots substitute officers at the German Economic Ministry Soon?

Source: Photo taken by author during the conference on Industrie 4.0 in the Ministry

At the International Fair on Industries Hanover (2018) the Festo-company has brought an innovative Robot-prototype-system to the market. This Bionic Workplace unifies Self-learning systems, Artificial Intelligence and automation solutions. The human operator works with a light weight bionic robot arm using hydraulics. The robot is controllable by movement, touch or speech. Similar digital innovations support the new initiative of Gates, B. (2018) presented at the Grand Challenges Meeting in Berlin to achieve progress and efficiency in the health sector.

“Intelligent” Products, Digitized Processes, and Artificial Intelligence

Digital technologies support the manufacturing and transportation of physical products by imbedding digital elements such as microchips in products (Qin J., Liu Y. and Grosvenor R. 2016). Sensors and processors collect and transmit data along the logistic chain as a feedback to the manufacturing machines and to the manufacturers. “Each raw product will contain a small embedded system equivalent to a miniature Web server with a wireless interface that serves as its digital product memory,” explains Wahlster, W. (2017) from the German Research Center for Artificial Intelligence. The transmitted results “learned by machines” allow immediate changes of the manufacturing process for improving products better covering the customers’ needs.

The intended industrial revolution in manufacturing will lead to a digitized system named the Internet of Things (IoT). Machine production will be networked by the use of Artificial Intelligence into a self-learning system. Product design, production planning and engineering, and the provision of services will be steered decentralized. (Nilsen, S., Nyberg, E. 2016)

Smart Factories

Industrie 4.0 technologies transform traditional factories and production sites to Intelligent or Smart Factories where all manufacturing resources like sensors, actuators, machines, robots, and conveyors etc. are interconnected. Information is automatically transmitted and increases technical and economic efficiency for the whole supply chain (Wahlster, W. 2017). The Smart Factory uses all information and is enabled to predict and maintain the machines working, to control the production process, and to manage the whole factory system. (German Trade and Invest Association, 2018)

At the Hanover Fair the Bosch Company has presented a prototype of a Smart Factory which is working with assembly lines in a modular structure thus being enabled to react automatically on new orders from customers. The automation concept is using a 5 G communication technology and receives energy from the ground via an inductive charging system (International Fair on Industries Hanover, 2018).

CHALLENGES FOR SMES DUE TO THE WEAKNESS OF THE STRATEGY

Financial Strains as a Basic Weakness of Industrie 4.0

For investing in digital reengineering the managers need additional financial funds. The Association for Financial Markets in Europe (2018, p.15) criticizes the “shortage of risk capital for high growth SMEs” as a weakness of the concept. About 80% of SMEs in Europe are financed by traditional bank credits. The association demands “Raising finance and retaining investors should be a top priority for industry and policy makers alike”. It recommends equity financing by the acquisition of venture capital investors,

by crowd funding and by cooperating with FinTech companies. SMEs are to use national and European support schemes, like the European Investment Fund and the German Start-up Fund (Association for Financial Markets in Europe (2018, pp. 16-19).

Weakness Due to a Fragmented Digitized Internet Infrastructure

The planned digitization of the whole chain of industrial production and logistics needs ICT-software and the access to physical transmission lines, net-works, servers etc. A functioning, efficient and secure digitized physical infrastructure is setting up the technological frame for innovative SMEs. Experts criticize the fragmented internet infrastructure in many rural regions in Europe, which is a weakness of Industrie 4.0 (Tyson J., 2018).

The infrastructure in Europe is generally state-owned and operated by large, profit oriented communication enterprises worldwide. The transmission lines and nets are set up by the Global Area Net (GAN) and the Wide Area Net (WAN). These consist of broadband networks, fiber wire lines, wireless connections, telecommunication satellites, and internet exchange points (IXP). Local servers, local connection points, routers and wireless connections at SMEs set up the Local Area Net (LAN). These enterprises in market economies demand a return on investment. To improve the internet infrastructure and the access for SMEs more public procurement programs and funds are to be launched.

Weakness Due to a Fragmented Digitized Energetic Infrastructure

Renewable energies and the digitization of energy systems are the driving forces of the digital revolution (Rifkin, J. 2015). SMEs need also access to a functioning, efficient and secure energetic infrastructure. Critics identify the fragmented energetic infrastructure and the unsolved storage problems in Europe as a weakness, too.

The ongoing digitization will increase energy demand. Billions of new devices get connected to the electricity network and thousands of new data centers and network services are getting installed over the next few years. The digitization of energy systems might enhance energy efficiency and compensate the expected increase of energy demand. Progress might also be achieved by the digitization of the power industry in Europe shifting to a balanced energy mix (Siemens, 2018). The internet platform of the German Energy Agency (2015) promotes renewable energies to cover increasing demand.

Threats by Technical Restrictions, Unskilled Labor Force and by Cyber Crime

Technical Restrictions and Unskilled Labor Force

In his thesis, Du Plessis, C. (2017) proposes to develop a standardized framework for implementing Industrie 4.0 on microeconomic level and to establish “learning factories”. His ambitious proposal is not yet approved by evidence on firm level and seems to underestimate investment costs and the technical compatibility problems. Distortions to the production process can be caused by incompatibilities between existing components and new digital components. Anderl, R. and Fleischer, J. (2017) accentuate the crucial technical challenges for the industrial digitization due to millions of small parts such as screws, nuts and rivets used for putting together equipment and machinery and for building facilities. To equip small parts with chips is technically or economically not convenient.

SMEs fear also the insufficient digital qualification of their labor force and the management. The German Government has launched the program Arbeit 4.0 to qualify employees.

Threats by Cyber Crime and Cyber War

The Industrie 4.0 technologies lead to a physically and digitally interconnection of devices, facilities and human users. The uncontrolled and unregulated use of the worldwide open broadband and the wireless telecommunication networks are making the transformed systems vulnerable against cyber crime and abuse (Balasingham, K. 2016). Cyber crime attacks by thousands of professional hackers can distort databanks and the energetic and digital infrastructure. Fundamental threats are caused by the grabbing of confidential business and administrative data, too.

Security experts of the North Atlantic Treaty Organization (NATO, 2017) have identified the crucial threats to the society of an open unsecured internet by the undeclared Cyber War. These technologies “enable disruptive behaviors,” imply a destabilization of the economy and “bring new hazards requiring an improved capacity for risk assessment and management” (NATO 2017, pp. 45-49). IT-experts have developed software for the encoding of confidential information, of data flows and data banks in such a way that only authorized users have access. Encoding cannot prevent physical interference and the hacking of codes and digital firewalls. Decentralized in-house solutions are to be given priority by the management before implementing Industrie 4.0.

SOLUTIONS AND RECOMMENDATIONS

Managers of SMEs planning to implement digital technologies are recommended to first assess their company and to conduct a SWOT- analysis. A feasibility study on the risks and benefits of an investment in digitization is to be followed by a master and action plan.

To stimulate innovative SMEs and to overcome financial strains public and private funding systems, tax reliefs, long term credits on digital business plans and the cooperation with FinTech-system are recommended. Newly founded holdings and cooperatives could build institutional bridges and enhance the collaboration between the digital world of Startups, technical universities and R&D institutes and the physical world of SMEs.

Against cyber crime software for encoding data transfer and the physical separation of local networks from the internet provide useful in-house solutions for SMEs.

For upgrading the poor official data base more data on the impact of the digital transformation on income, risks, costs of SMEs and on employment are to be officially provided.

Politicians are recommended to improve and modernize the fragmented digital and physical infrastructure by more public investment and a reallocation of public expenditures.

FUTURE RESEARCH DIRECTIONS

Future macroeconomic research is needed on the net added value of digitization in different sectors and on income and employment by applying the cost-benefit-analysis (Roland Berger, 2016 publ.).

Future microeconomic research is recommended on international comparable case studies and on the analysis of the impact of digitization on business risks and benefits for SMEs (Nilsen, S., Nyberg,

E. (2016). Research is needed to design standards and to design assessments, feasibility studies, master-plans, and action plans on digitization on firm level. R&D is to focus on pilot projects, “small steps”, and the implementation of components of Industrie 4.0.

The monitoring and analysis of ongoing larger projects is recommended, e.g. the Siemens-EU project Internet of Things at Work and the Open Integrated Factory with integrated intelligent work pieces of the software manufacturer SAP (International Fair on Industries Hanover, 2018).

R&D is needed on encrypting and on physical innovations to protect against fraud and criminal activities by professional hackers. R&D is also to be focused on the physical internet, on power lines, on local digital networks, on local grids for production, and on in-house solutions.

CONCLUSION

The digital transformation is still at its beginning. Many digital technologies have been developed and brought to the market made available to SMEs in manufacturing industries. Most SMEs still hesitate to implement the Industrie 4.0 strategy of the German Government and the EU Commission and to transform traditional industrial manufacturing into Cyber Physical Systems. The situation in each company is different. Company managers can use the methodology of the SWOT- and cost-benefit-analysis to assess the strength, weakness, opportunities, and challenges for their companies before investment. SMEs have to take care especially on financial strains, investment risks, and the discrepancies between digital innovations and business needs of traditional manufacturing.

The fragmented internet and energetic infrastructure in Europe and Cyber Crime are a crucial challenge to be overcome. Politicians are to support the transformation and to boost public investment for modernizing the infrastructure and for securing the internet against cyber crime. For measuring the impact of digitization on the economy more accurate data on costs and benefits are to be officially provided.

Startups, the academic world and SMEs need new concepts of institutional collaboration and for setting up step by step procedures for a successful digital transformation of all economic sectors taking care on labor force.

KEY TERMS AND DEFINITIONS

3D Printer Technology: Can apply all types of pulverized solid materials, including pulverized metals, for printing physical products also of large size.

Additive Manufacturing: Describes a digitized production process and digitized products in manufacturing.

Cyber Physical Systems: Are being set up by the internet of things that are machines, employees, products, and products facilities being digitally interconnected by the internet.

Digital Infrastructure: Is set up by digital software, servers, and physical global and local networks.

Energetic Infrastructure: Is set up by power stations, long range power lines and regional and local grids for electricity.

Industrie 4.0: Is a German term used as a name of an official internet platform and as a label of digital technologies in manufacturing industries.

Robotics: Deals with the design, construction, operation, and application of robots and the computer systems for their control information processing.

Smart Factories: Are digitized intelligent factories using additive manufacturing and robotics.

INTRODUCTION

The study of the effects of IT investments on firm's performance has been a critical issue for research since the late 1980s. Different financial models have been used to clarify the contribution of IT investments, e.g. options theory (Fichman, 2004) and Edwards - Bell - Ohlson model (Dehning et al., 2005; Muhanna & Stoel, 2010). Some researchers rely on market prices (Dos Santos et al., 1993; Kim et al., 2001; Otim et al., 2012), while others measure the effect on financial ratios (Amit & Shoemaker, 1993; Melville et al., 2004; Wade & Hulland, 2004).

This work aims to provide additional insights regarding the influence of IT resources on performance. To do that, a new measure of performance is proposed that goes beyond the well-accepted profit. Several new links between IT literature, organization theory and financial theory are elicited.

BACKGROUND

Early studies assumed that IT investments would improve productivity (Bresnahan & Tajtenberg, 1996); however, these results were inconclusive (Morrison & Berndt, 1990; Siegel & Griliches, 1991; Loveman, 1994) and new research frameworks were explored (Melville & Kraemer, 2004). Recent research generally report effects on firm value, shareholders' wealth (Dos Santos et al., 1993; Im et al., 2001), financial measures (Brynjolfsson & Hitt, 1996; Kudyba & Diwan, 2002; Piñeiro, 2006), innovation (Drucker, 1988; Osterman, 1991; Phan, 2003; Gharavi et al., 2004) and risk-mitigation (Otim et al., 2012).

However, these outcomes seem to be contingent (Dos Santos et al., 1992; Im et al., 2001; Dehning & Richardson, 2002). Several mediating factors have been identified: business processes (Dehning & Richardson, 2002; Melville et al., 2004), knowledge (Sambamurthy et al., 2003), experience and IT management skills (Damanpour & Evan, 1984; Neirotti & Paolucci, 2012), organizational capabilities (Nevo & Wade, 2010; Ravinchandran & Lertwongsatien, 2005), dynamic capabilities (Teece et al., 1997; Eisenhardt & Martin, 2000), financial capacity (Harris & Kaatz, 1989), firm's size and industry (Dos Santos et al., 1993; Im et al., 2001), R&D (Jacobson, 1990; Bharadwaj et al., 1999; Holsapple & Wu, 2011), and real options (Fichman, 2004; Sambamurthy & Bharadwaj, 2003). Time lags and accumulation effects (Kudyba & Diwan, 2002; Cron & Sobol, 1983) are also present.

These findings are consistent with the predictions of the Resource-Based View (RBV) (Barney, 1991; Amit & Shoemaker, 1993; Peteraf, 1993): some firms outperform others because they have both potentially valuable resources (infrastructure and software platforms, financial resources, etc.) and a

DOI: 10.4018/978-1-7998-3473-1.ch107

suitable set of complementary capabilities (e.g. relational capital, reputation, flexibility, ability to manage complex structures, management quality, and dynamic capabilities).

The competitive potential of a resource depends on several attributes: *value* (i.e., the opportunities it offers to seize opportunities or mitigate risks), *rarity and scarceness* (cost and accessibility) and *protection* against imitation and mobility (embeddedness, network effects, complementarity, path-dependence, etc.).

For a long time, IT platforms were the focus of managers and researchers, because they are at the core of IT inside-out resources; however they are also imitable, accessible and generally cheap (Barney, 1991), and are not expected to deliver competitive advantage, unless they are leveraged by abilities (Nevo & Wade, 2010). Assets must be deployed in a suitable organizational context (Damanpour & Evan, 1984; Teece et al., 1997; Nevo & Wade, 2010) and leveraged by internal abilities, e.g. management skills (Damanpour & Evan, 1984, Mingfang & Ye, 1999; Neirotti & Paolucci, 2012), and online information capabilities (OIC) (Barua et al., 2004), to benefit from path dependence and embeddedness (Barney, 1991).

The Net-enabled business transformation (Straub & Watson, 2001) involves radical changes in the organization of the information flows (Gharavi et al., 2004). The Internet channels a large amount of multimedia (Daft & Lengel, 1986), supports internal processes (Poon & Swatman, 1995), helps the company to manage outsourced activities (Poon & Swatman, 1995; Teo & Pian, 2003; Day, 1994; Bharadwaj, 2000), allows for greater flexibility (Bhatt et al., 2010) and supports the development external intangibles, e.g. reputation and loyalty (Roberts & Grover, 2012; Barua et al., 2004).

It is useful to identify different patterns of use of the Internet resources. Passive patterns include the use of the Net to ease internal communications and/or support virtual teams; active patterns change tasks, information links, and the business model. Companies are expected to *evolve* from passive into active patterns (Nelson & Winter, 1982).

Finally, dynamic capabilities allow the company to face changes in the environment (Teece et al., 1997; Straub & Watson, 2001); flexibility is needed to embrace technical progress, to manage external partnerships and to assimilate changes in value chain (Bhatt et al., 2010; Roberts & Grover, 2012). Previous works report a positive relationship between IT decentralization, flexibility and performance (Leifer, 1988; Zeffane, 1992)

FOCUS OF THE ARTICLE

The paper explores the effects of IT on firm's performance by considering several resources and capabilities, and their respective interactions. The underlying research model connects long-term performance (as measured by the risk of bankruptcy) to several IT resources and capabilities, with some moderating factors and financial controls (Figure 1). It goes beyond traditional performance measures, to depict a complete picture of the benefits a company can expect.

The following hypothesis are suggested:

- H1. Standard IT resources have a negligible effect on the risk of bankruptcy, *ceteris paribus* capabilities
- H2: The use of proprietary software has a direct negative effect on the risk of bankruptcy
- H3: Synergies between complementary IT resources and capabilities have a direct negative effect on the risk of bankruptcy.
- H4. IT management capabilities have a direct negative effect on the risk of bankruptcy
- H5. Collaboration capabilities have a direct negative effect on the risk of bankruptcy

Figure 1. Research model

H6. Intensity of use of the Internet has a direct negative effect on the risk of bankruptcy

H7: Flexibility has a negative direct effect on risk of bankruptcy

To examine these hypothesis, a random selection of firms was sampled in 2003. Companies were observed until 2013, checking if they went bankrupt and controlling for mergers and acquisitions. A factor analysis is performed to reduce the dimension of the problem; then, a logit model is fitted to assess individual effects:

$$p = P(Y_j = 1) = \frac{1}{1 + e^{-[\beta_0 + \beta_1 \cdot X_{1j} + \beta_2 \cdot X_{2j} + \dots + \beta_n \cdot X_{nj}]}}$$

where Y_j is the status of the company (healthy vs. bankrupt) and X_{hj} ($h=1..n$) are IT resources.

DATA

This research uses a combination of public financial information and privately gathered survey information about IT resources. Financial ratios were calculated from the accounting data obtained from the Mercantile Registry; IT resources were assessed through questionnaires and personal interviews (CEO and/or CIO). Response rate was 28%, similar to that of previous studies (e.g. Teo & Pian, 2003).

Dependent Variable

Gauging corporate performance is conflictive. It has been argued that RBV might be not testable because the theory stands on an imprecise definition of *value* (Priem & Butler, 2001). Financial theory defines value as a complex notion combining the cash flows of current assets, the additional cash flows of future investments, risk and time (Makadok, 2001).

This paper suggests that *the risk of filing for bankruptcy* is a suitable and reliable measure of corporate performance. This definition provides several advantages to researchers and practitioners: while value is to greater or lesser degree subjective (depends on expectations and forecasts), bankruptcy is a fact, and it is connected to firm's performance: companies fail because they are unable to perform as well as rivals.

The dependent variable equals one if the company has filed for bankruptcy, and equals zero if not.

Independent Variables

As the paper rests on a cross-sectional sample, independent variables were designed to capture generic IT resources. They are grouped into three categories: IT resources, IT capabilities, and other capabilities

Table 1. Definition of the independent variables

Variable	Meaning	Specification	IT resources and capabilities
intes	Internal IT infrastructure	3 categories	IT resources: infrastructure, communications, proprietary technology
extes	External IT structure	2 categories	
sw	Software	4 categories	
exptic	Time from 1 st relevant IT investment	Continuous	IT capabilities: business systems thinking, ability to manage IT resources, responsiveness
imptic	Perceived importance of IT for the business	4 categories	IT capabilities: IT and business synergy, business/IT strategic thinking, IT assimilation, market responsiveness
impint	Perceived importance of the Internet for the business	4 categories	
intad	Using the internet to disseminate business information	Binary	OIC: market responsiveness, business/IT strategic thinking, efficiency, customer service, developing knowledge assets
b2c	B2C activities	Binary	
b2b	B2B (EDI / e-marketplaces)	Binary	
nsha	Number of shareholders	Continuous	Management skills, internal control
age	Age	Continuous	
auton	User autonomy, devolution	4 categories	ability to coordinate, ability to learn, flexibility, responsiveness, using knowledge assets
decen	Decentralization	4 categories	
group	Group and/or collaborative activities	Binary	
grper	Stable teams	Binary	

Table 2. Control variables

Variable	Meaning	Specification
assts	Book value of assets	Continuous
shfnd	Book value of the firm	Continuous
levg	Leverage	Continuous
liq	Liquidity	Continuous
roa	Return on Assets	Continuous
indus	Industry	5 categories

(Table 1, Table 2). Let us emphasize that the research model required data to be collected in 2003; hence, some recent advances (e.g. online social networks, e-marketplaces, m-commerce) are not considered.

Hardware and software are described by two categorical variables (INTES and SW); EXTES offers insights about external electronic linkages, e.g. Internet, e-mail, videoconference, and information services.

Two variables are used to measure flexibility (Gul & Chia, 1994; Choe, 1998): decentralization and autonomy. Decentralization (DECEN) measures physical dissemination, while Autonomy (AUTON) expresses the malleability of tasks and processes.

The use of the Internet and on-line information abilities are described by several variables. INTAD equals 1 if the company uses the Internet to spread corporate information, and zero otherwise; B2B (B2C) equals 1 if the company was conducting B2B (B2C), and zero if not.

Drawing on previous literature, developed several proxies for *human IT resources* (Melville et al., 2004) were developed. All of them assume that capabilities are an outcome of *active learning*, and emphasize collaboration (Ahuja, 2000; Blomquist & Levy, 2006).

Firm's age (AGE) may offer some insights about management skills (Nelson & Winter, 1982). However, assessing management quality is controversial because of information asymmetry and path dependence. Instead, indirect measures can be used: recent works have found that the risk of bankruptcy is inversely related to the number of *different* shareholders (NSHA) (Piñeiro et al., 2012).

Managers were asked to measure the importance of IT (IMPTIC) and the Internet (IMPINT) for their business. These variables are expected to express business/IT strategic thinking, the ability to manage IT projects, IT awareness, and IT technical skills.

As noted above, collaboration allows the company to transfer knowledge and build a shared view of the business (Gul & Chia, 1994; Brodbeck et al., 2008). GROUP equals one if there is a formal plan to facilitate collaboration throughout the company, and zero otherwise; GRPER equals one if some specific management tasks are performed by permanent teams invested with power to decide and control, and zero if not. GROUP and GRPER are expected to be closely related to flexibility.

Control Variables

Financial situation is expected to modify the availability and/or the outcomes of IT resources, therefore confounding bias must be addressed. Several magnitudes have been considered: total assets (ASSTS) and equity capital (SHFND) measure the size of the firm; return on assets (ROA) summarizes the ability of the company to generate profit, and leverage (LEVG) and current ratio (LIQ) are critical indicators of insolvency risk. Industry (INDUS) may be relevant too.

FINDINGS

27.6% of the sampled companies went bankrupt between 2003 and 2012. Healthy firms were found to be more decentralized, more likely to have high levels of user autonomy, collaboration and IT expertise, and are more prone to develop Internet-based business processes.

Given the number of variables, a factor analysis was performed. The KMO test is acceptable (KMO = 0,671), and the Bartlett's test of sphericity indicated that data is suitable for a factor analysis ($\chi^2 = 653.208$; $p = 0.000$). Six factors were extracted (eigenvalue > 1) with varimax rotation; the Chi-Square goodness-of-fit statistic is 41.611 ($p = 0.358$), so the original variables are adequately described by the factor model. Communalities are very high (> 85%) for INTES, EXTES, DECEN, B2B, and INTAD.

Factor loadings are summarized in Table 3 (values below 0.2 omitted for brevity). Factor 1 synthesizes IT infrastructure (*Internal Infrastructure*); factor 2 (*Basic Internet Resources*) summarizes the resources needed to develop business processes over the Internet; AGE, EXPTIC and NSHA are present in factor 3 (*Management abilities*); factor 4 involves e-business (*e-Business*); factor 5 (*Collaboration*) summarizes collaboration-oriented resources and software platform; finally, factor 6 (*Flexibility*) involves user

Table 3. Rotated factors matrix

	Factor					
	1	2	3	4	5	6

AUTON						.695
DECEN	.879					
GROUP					.619	
GRPER				.256	.627	

autonomy and software infrastructure. It is useful to view these factors as *bundles* of interdependent IT resources and capabilities [69].

Each firm is now described by six synthetic factors; their values are obtained by multiplying the original variables by the coefficients showed in Table 4. For example Factor 1 can be expressed as

$F1 = 0,352 \cdot \text{INTES} + 0,327 \cdot \text{EXTES} + 0,031 \cdot \text{SW} + \dots + 0,005 \cdot \text{GROUP} + (-0,077) \cdot \text{GRPER}$ —where INTES equals one if user devices are isolated, two if they are dumb terminals connected to a server, and so on (see footnote 3).

Factor analysis is intended for use with continuous variables with a multivariate normal distribution; the use of categorical values is not extraordinary, however a two-step cluster analysis was run to test the robustness and reliability of the factors. IT resources can be grouped into five clusters (Figure 2) with adequate levels of cohesion and separation (average silhouette width = 0.7); clusters and factors are qualitatively similar.

Then, for prepared data, a parsimonious logit model was fitted. Independent variables were presented into three blocks: financials, IT resources, and interactions between resources and capabilities (Table 4). Interaction terms were designed following previous research on IT and performance:

Table 4. Factor score coefficient matrix

- *Management Abilities* by *Basic Internet Resources*, *e-Business*, *Collaboration*, and *Flexibility*.

Basic Internet Resources by e-Business

The Hosmer and Lemeshow test (Table 5) shows that the logit model adequately fits the data ($\chi^2 = 7.870$; $p = 0.446$); omnibus tests are also significant ($\chi^2 = 61.82$; $p = 0.000$), and R^2 indicates that the model explains a large portion of firm's performance (as measured by bankruptcy risk). Hit rate is also high (86.7%).

Once controlled for leverage, four IT constructs and one interaction term are found to be significant (Figure 3):

Table 5. Results of the logit regression

- *Flexibility* turns out to be the most relevant IT resource ($B = -3.151$, $p < 0.01$).
- *Basic Internet resources* are significant at 5 per cent level, with the expected negative sign ($B = -1.133$, $p < 0.05$)
- *Collaboration* is also found to be significant at 5 per cent level ($B = -1.058$, $p < 0.05$)
- *Management Abilities* (management quality and IT experience) are found to be significant at 1 per cent level ($B = -0.8$, $p < 0.05$).

- Two interactions are found to be significant: the coefficient on *Management Abilities* by *e-Business* is expected to be negative and significant ($p < 0.05$); *Internal infrastructure* by *Flexibility* has the expected negative sign, although the evidence is weak ($p < 0.1$).

According to Table 6, flexibility can be viewed as the combination of an ability (user autonomy) and an IT asset (software infrastructure); the model also suggests that flexibility is enabled by decentralization. It's a dynamic capability (Teece et al., 1997) needed to carry out innovation, to manage external partnerships and to integrate outsourced activities (Bhatt et al., 2010; Roberts & Grover, 2012). This strongly supports hypothesis No. 7.

Proprietary software is tailored and embedded in business processes; hence, it offers protection against imitation. These findings suggest that the use of custom software has a measurable positive effect on firm's performance, as predicted by the RBV and hypothesis No. 2.

As noted above, *Basic Internet resources* is a compact bundle of common Internet assets (e.g. software and equipment), internal skills (IT management skills, ability to manage IT changes) and outside-in resources (e.g. market responsiveness) (Bharadwaj, 2000). The results suggest that a more intense use of *Basic Internet resources* improves performance and mitigates the risk that a company goes bankrupt (Barua et al., 2004; Teo & Pian, 2003).

Management Abilities is found to be significant, with a negative estimate: age, previous experience in the management IT-intensive projects, and the number of shareholders have substantial and positive loadings on this factor; hence, these pieces of intellectual capital reduce the average risk of bankruptcy (i.e., increase firm's performance), ceteris paribus, as hypothesis No. 4 predicted.

Collaboration is closely related to management skills, flexibility, organizational responsiveness, and knowledge transfer. The results indicate that a higher level of collaboration between individuals, groups and organizational units is expected to reduce the odds of filing for bankruptcy (i.e., is expected to increase performance): therefore, hypothesis No. 5 was supported.

It must be noted that risk mitigation does not emerge as a consequence of *just* the adoption of IT and/or the implementation of e-commerce projects: firms need to leverage platforms with suitable internal abilities and external invisible assets. These results provide strong support for both the design of the factors (*bundles* of resources) and hypothesis No. 3: synergies between IT resources and capabilities are needed, and complementarities have a significant effect on performance (as measured by the risk of bankruptcy).

The effect of each original variable can be gauged considering both the logit estimates (Table 5) and factor scores (Table 4). Let us consider a 16.7 year old company with a single shareholder and a leverage ratio of 34.5%; a computer-based LAN and commercial software are available; managers attach high importance to IT but the firm does not perform electronic commerce; user autonomy is very low, and no collaboration plans have been developed. According to the model, the probability of the company going bankrupt is 1.79%. A similar firm that conducts e-commerce and uses some pieces of proprietary software would have an estimated risk of 14.6% - as a consequence of the volatility of Internet-based businesses.

SOLUTIONS AND RECOMMENDATIONS

From a practitioner's point of view, the critical question is whether IT investments will result in higher performance. Managers tend to evaluate investments on a standalone basis, i.e., as if they were isolated and independent projects, to clearly define the boundaries of the problem and mitigate uncertainty.

Figure 3. Summary of hypotheses and results

When supplementary resources are needed, this strategy can result in an increased likelihood of errors in capital budgeting decisions, and in an inefficient resource allocation.

The results also stress the role of intangible resources, such as management abilities or IT expertise. It has been repeatedly asserted that technology is just an enabler, and that additional skills and invisible assets are needed to benefit from IT infrastructure; this work offers evidence that coherent bundles can be identified, where IT resources are leveraged by some specific internal abilities and external intangibles.

Finally, this work proves that long-term performance can be measured reliably as the risk a company goes bankrupt. Financial failure is the consequence of a combination of reasons that causes underperformance and loss of competitiveness. Bankruptcy is a clear and accessible baseline for managers, and an objective fact for researchers.

FUTURE RESEARCH DIRECTIONS

The paper leaves several questions for future research. It might be useful to explore the effect of mature e-business projects and recent innovations (e.g. social networks, mobile commerce, and e-procurement), which were not present when primary data were collected. It also would be beneficial to apply the methodology to banking and financial services, where IT resources are strategically critical but competition is limited by regulation.

CONCLUSION

The RBV predicts that firm's performance is driven by the availability of suitable and complementary IT resources and capabilities. This work extends this view by offering i) a catalogue of relevant IT resources and capabilities; and ii) measures of their respective effect on firm's performance. To do that, a new objective and exhaustive definition of performance is suggested.

Four main conclusions can be derived from the results: i) performance (and the risk of going bankrupt) is driven by the availability of concrete IT resources and capabilities; ii) assets and abilities can

be grouped into bundles; iii) complementarities and synergies do exist, and have a measurable effect on performance; and iv) the risk of going bankrupt is a reliable measure of firm's performance.

KEY TERMS AND DEFINITIONS

Bankruptcy: The legal status of a firm that is unable to meet payments due to massive and irreversible financial imbalances.

Capability: A skill or aptitude that confers to the company a potential capacity to carry out activities or projects with an abnormally high levels of quality and/or performance.

Performance: An assessment of how well a company is doing, often measured against financial or competitive goals.

Resource: A tangible or intangible mean to which value is attributed because it is required to perform an activity.

Risk: The inability to know in detail all the relevant factors of a problem and to forecast with certainty the outcomes of a decision, due to imperfect and incomplete information.

ENDNOTES

¹ Sampling error is 4.9%.

² Categorical variables were defined as follows:

INTES: 1 = without LAN; 2 = *dumb* terminals network; 3 = PC-based network

EXTES: 1 = not connected to the Internet ; 2 = connected to the Internet

DECEN: 1 = centralized; 2 = low; 3 = medium; 4 = very decentralized

SW: 1 = Mostly commercial; 2 = mixed, with a high proportion of commercial SW; 3 = mixed, with a high proportion of proprietary SW; 4 = mostly proprietary.

AUTON, IMPTIC and IMPINT: 1 = none; 2 = low; 3 = medium; 4 = high

³ Industry was defined as follows: 1 = Agriculture & fishing; 2 = Extractive & building; 3 = Industry; 4 = Commerce; 5 = Services.

Role of Technology Startups in Africa's Digital Ecosystem

Benjamin Enahoro Assay

Delta State Polytechnic, Ogwashi-Uku, Nigeria

INTRODUCTION

The era in which we live is dominated by technology. Technology has continued to revolutionize the way people interact with one another, as well as conduct the operations of business on a regular basis (Decaux, 2018, Ogunfuwa, 2018; Osuagwu, 2019). Small and big businesses need technology to thrive. Businesses are growing and expanding across countries due to technological advancements. It is technology that gives organizations the strength to spread their wings. Oak (2018), notes that if not for technology, complex industrial processes would not have been carried out, and large-scale production of goods would have been impossible. Growing businesses create employment opportunities for people and technology plays a big role in business growth.

Apart from helping to shape the way things are done, technology has brought innovations into service delivery thus enabling human society to transform to a technology driven world where almost everything is being automated. Technology automates the most complex of processes, be it in communication, education, medicine or any other industry. With the application of technology, critical and time-consuming processes can be executed with ease and in less time. Laborious and repetitive tasks are best done by machines. People do not have to slog as much as they would have had to, if not for technology. With automation came efficiency and speed. They save human effort and time to a great extent and make life easy and comfortable.

Human life and technology cannot be separated, hence society has a cyclical co-dependence on technology (Risto, 2000). However, technology has also caused humans concerns. Its poor application has resulted in the pollution of the environment and it has also caused serious threat to lives and society. This therefore calls for proper use of technology. The biggest challenge facing mankind is to determine the type of future they need to have and then create relevant technologies that will simplify the way things are done.

In the last few years in Africa, technology startups have been developing software solutions which companies and organizations are leveraging on to improve service delivery, as well as address societal challenges. On a large scale, these efforts are geared towards closing the technological divide between Africa and Europe. Experts have noted that the growth potential for technology in the African continent is huge, judging by the remarkable breakthrough these startups are making in addressing workplace issues and getting many youths meaningfully engaged (Aliogo, 2018, p.29; Essien, 2018,p.81).

In the African context, technology innovation is seen as an option out of poverty, and most technology hubs in the continent are providing communities with infrastructures to support home-grown innovations. Startups require less infrastructures and financial risk for rapid growth than big industries. These hubs are not only providing startups with the technical support and access to fast internet, and free training but they also provide professional and social networks in which these technology entrepreneurs can thrive.

DOI: 10.4018/978-1-7998-3473-1.ch108

A report by social media week shows that regardless of the growth of internet usage in Africa since 2000, only a segment of the population (about 7 percent) have access to internet. Even with the increase in access to technology globally, the divide in knowledge and skill still limits the ability of developing countries to compete in the global market. The report also stated that the digital divide is the gap in the access to information and communication technologies between developed and developing countries or among different social groups (Aliogo, 2018). The divide is not limited to internet access but also to mobile phones, computers, radio and television. Access to information and computer technology is crucial to sustainable economic and social development as well as environmental protection.

A particular report cited by Aliogo (2018) noted that Africa is at the start of technological renaissance. The report said seven out of the 10 of the world's fastest growing internet populations are in Africa. This trend is expected to re-shape the entire economies of the continent as new companies would leapfrog established technology, ideas and infrastructure to grow. It also stated that internet penetration in the continent is just 29 percent which implies that the majority of growth and network effects are still to come.

There has been a boom in tech startups and funding in the continent. The rise reflects the rapidly developing tech sector in Africa. In 2016, Africa technology startups raised in record-breaking total of \$366.8m in investment, according to San Francisco headquartered venture capital firm Partech Ventures. To put this into perspective, tech companies across the continent raised \$276.5m in the previous year (2015). Partech Ventures data only includes deals higher than \$200,000 and excludes any grant or debt deals, and "megadeals" worth \$100m and over. Only three countries accounted for annual 80 percent of Africa's total funding, with Nigeria securing \$109m or 29.8 percent; South Africa receiving \$96m or 26.4 percent; and Kenya securing \$92m or 25.3 percent.

The average size of the deals struck in Africa by startups also increased year-on-year at every stage of investment, with series A funding, for example, increasing to around \$3.7m. Series A refers to a company's first significant round of venture capital financing. At the same time, the number of tech hubs in Africa rose to 310, with 173 accelerators and incubators recorded in 2016, according to the World Bank. In the previous year (2015), there were 117. The number of tech hubs rose from 310 to 442 in 2018.

The growth in Africa's technology sector came at a time when mobile internet adoption continued to grow rapidly, with the number of mobile internet subscribers increasing threefold in the last six years to over 300m unique users, according to the mobile operator's trade body GSMA. Additional 250m subscribers are expected by 2020. Mobile internet is the platform of choice in Africa due to its relatively low cost when compared to wireless broadband. The growing uptake in mobile technology has fuelled many of the innovative digital solutions and services emerging from the continent, and, as mobile infrastructure advances and the cost of smart devices falls, technology entrepreneurs are developing uniquely African technology solutions to African problems.

The objectives of the article are:

1. To identify the role technology startups are playing in Africa's digital ecosystem.
2. To identify the challenges confronting African technology startups and how to solve them.
3. To recommend ways to promote the growth and development of technology startups in the continent.

BACKGROUND

Overview of Startups

The importance of startups to business and society cannot be over emphasized. A startup is a newly emerged business venture that aims to develop a viable business model to meet a market place need or problem. Founders design startups to effectively develop and validate a scalable business model (Robehmed, 2013; Katila et al., 2012). The concepts of startups and entrepreneurship may appear similar, but they are not the same. While entrepreneurship refers to all new businesses, including self-employment and businesses that never intend to grow big or become registered, startups are new businesses that intend to grow beyond the solo founder, have employees, and grow large.

Everywhere, startups face high uncertainty and do have high rates of failure, but the few that survive to become successful companies have the potential to become large and influential (Schmitt, 2018; Griffith, 2014). Some startups become Unicorns, that is, privately held startup companies valued at \$1billion. According to Tech Crunch, there were 279 unicorns as of March 2018, with most of the unicorns located in China, followed by the United States. The largest unicorns founded as of October 2018 included Ant Financial, ByteDance, DiDi, Uber, Xiaomi, and Airbnb.

Startups usually evolve through the effort of a founder (Solo founder) or co-founder who are determined to solve a problem. The founder(s) of a startup begin market validation with problem interview, solution interview, and then build a minimum viable product (MVP), that is, a prototype, to develop and validate the business models. The startup process can take a long period of time, by one estimate, three years or longer (Carter et al., 1996; Reynolds & Miller, 1992), and hence sustaining effort is required. However, sustaining effort over the long term is especially challenging because of the high failure rates and uncertain outcomes (Uy et al., 2015).

Startup Principles

There are many principles in creating startups. They include:

Lean Startup

Lean startup is a popular set up of principles used in creating and designing startups under a limited resources and tremendous uncertainty to build their ventures more flexibly and at lower cost. It is based on the idea that entrepreneurs can make their implicit assumptions about how their ventures works explicitly and empirically test them (Van Burg et al, 2008). The empirical test is to de-validate these assumptions and to get an engaged understanding of the business model of the new ventures, and in doing so, the new ventures are created iteratively in a build-measure-learnloop. Hence, lean startup is a set of principle for entrepreneurial learning and business model design. More specifically, it is a set of design principles aimed at repetitive experiential learning model design under uncertainty in an engaged empirical manner.

Typically, lean startup focuses on a few lean principles.

1. Find a problem worth solving, then define s solution
2. Engage early adopters for market validation
3. Continually test with smaller, faster iterations
4. Build a function, measure customer response, and verify/ refuse the idea
5. Evidence – based decisions on when to “pivot” by changing your plan’s course
6. Maximize the efforts for speed, learning and focus

Market Validation

A key principle of startup is to validate the market need before building a solution. Because startups are uncertain, you do not want to waste time or money building something that has weak demand. Validating your ideas before deciding to invest heavily in building something is a wise move no matter how confident you are. One may think a major problem has been solved, but does the market care enough to invest in it themselves? Being overconfident in an idea and failing to validate it early takes on unnecessary risk.

Design Thinking

Design thinking is used to understand the customers' need in an engaged manner. Design thinking and customer development can be biased, because they do not remove the risk of bias because the same biases will manifest themselves in the sources of information, the type of information sought, and the interpretation of that information (York & Danes, 2015). Encouraging people to “consider the opposite” of whatever decision they are about to make tends to reduce biases such as overconfidence, the hindsight bias, and anchoring (Larrick, 2004; Mussweiler, Strack, & Pfeiffer, 2000).

Decision-Making Under Uncertainty

In startups, many decisions are made under uncertainty (Schmitt, 2018), and hence a key principle for startups to be agile and flexible. Founders can embed options to design startups in flexible manners, so that the startups can change easily in future.

Uncertainty can vary within-person and between-person. A study found that when entrepreneurs feel more uncertain, they identify more opportunities (within-person difference) but entrepreneurs who perceive more uncertainties than others do not identify more opportunities than others do (no between-person difference) (Schmitt, 2018).

Partnering

Startups may form partnerships with other firms to enable their business model to operate (Teece, 2010). To become attractive to other businesses, startups need to align their internal features, such as management style and products with the market situation. In their 2013 study, Kask and Linton develop two ideal profiles, or also known as configurations or archetypes, for startups that are commercializing inventions. The inheritor profile calls for a management style that is not too entrepreneurial (more conservative) and the startup should have an incremental invention (building on a previous standard). This profile is set out to be more successful (in finding a business partner) in a market that has a dominant design (a clear standard is applied in this market). In contrast this profile is the originator which has a management style that is highly entrepreneurial and in which a radical invention or a disruptive innovation (totally new standard) is being developed. This profile is set up to be more successful (in finding a business partner) in a market that does not have a dominant design (established standard). New startups should align themselves to one of the profiles when commercializing an invention to be able to find and be attractive to a business partner. By finding a business partner, a startup has greater chances of becoming successful (Kask & Linton, 2013).

Startups usually need different partners to realize their business idea. The commercialization process is often a bumpy road with iterations and new insights during the process. Hasche & Linton (2018)

argue that startups can learn from their relationships with other firms, even if the relationship ends, the startup could have gained valuable knowledge about how it should move on. When a relationship is failing for a startup it needs to make changes. Three types of changes have been identified by Hasche and Linton (2018).

1. Change of business concept for the startup
2. Change of collaboration constellation (change several relationships)
3. Change of characteristics of business relationship (with the partner, e.g. from a transactional relationship to more of a collaborative type of relationship)

Entrepreneurial Learning

Startups need to learn at a huge speed before running out of resources. Proactive actions (experimentation, searching, etc) enhances a founder's learning to startup a company (Castrogiovanni, 1996). To learn effectively, founders often formulate falsifiable hypotheses, build a minimum viable product (MVP) and conduct A/B testing.

Business Model Design

With the key learning from market validation, design thinking and lean startup, founders can design a business model. However, it is important not to dive into business models too early before there is sufficient learning on market validation. While elucidating this, Paul Graham of Y Combinator said "what I tell founders is not to sweat the business model too much at first. The most important task at first is to build something people want. If you do not do that, it won't matter how clever your business model is"

Startup Ecosystem

The size and maturity of the startup ecosystem is where a startup is launched and where it grows to have an effect on the volume and success of the startups. The startup ecosystem consists of the individuals (entrepreneur, venture capitalists, angel investors, mentors, advisors); institutions and organizations (top research universities and institutes, business schools and entrepreneurship programs and centres operated by universities and colleges, non-profit entrepreneurship support organizations, government entrepreneurship programs and services, chambers of commerce) business incubators and business accelerators and top-performing entrepreneurial firms and startups. A region with all of these elements is considered to be a "strong" startup ecosystem. One of the most famous startup ecosystems is Silicon Valley in California, where major computer and internet firms and top universities such as Stanford University create a stimulating startup environment, Boston (where Massachusetts Institute of Technology is located) and Berlin, home of WISTA (a top research area), numerous creative industries, leading entrepreneurs and startup firms.

Although there are startups created in all types of businesses, and all over the world, some locations and business sectors are particularly associated with startup companies. The internet bubble of the late 1990s was associated with huge numbers of internet startups companies, some selling the technology to provide services. Most of this startup activity was located in the most well known startup ecosystem – Silicon Valley, an area of northern California renowned for the high level of startup company activity.

Gromov (2010) notes that:

The spark that set off the explosive boom of “Silicon startups” in Stanford Industrial Park was a personal dispute in 1957 between employees of Shockley semiconductor and the company’s namesake and founder, Nobel Laureate and co-inventor of the transistor William Shockley ... (His employees) formed Fairchild semiconductor immediately following their departure ... After several years, Fairchild gained its footing, becoming a formidable presence in this sector. Its founders began learning to start companies based on their latest ideas and were followed on this path by their own former leading employees ... The process gained momentum and what had once began in a Stanford’s research park became a veritable startup avalanche ... Thus, over the course of just 20 years, a mere eight of Shockley’s former employees gave forth 65 new enterprises, which then went on to do the same.

Startup advocates are also trying to build a community of tech startups in New York city with organizations like NY Tech Meet Up and build in NYC. In the early 2000s, the patent assets of failed startup companies are being purchased by what are derogatorily known as patent trolls, who then take the patents from the companies and assert those patents against companies that might be infringing the technology covered by the patent (McDonough, 2007)

Startup Investing

Startup investing is the action of making an investment in an early-stage company (the startup company). Beyond founder’s own contributions, some startups raise additional investment at some or several stages of their growth. Not all startups trying to raise investments are successful in their fundraising. In the United States, the solicitation of funds become easier for startups as a result of the JOBS Act (The Wall Street Journal, 2013; Financial Times, 2013; Bloomberg Businessweek, 2013; Venturebeat, 2013).

Prior to the advent of equity crowd funding, a form of online investing that has been legalized in several nations, startups did not advertise themselves to the general public as investment opportunities until they first obtained approval from regulators for an initial public offering (IPO) that typically involved a listing of the startups securities on a stock exchange. Today, there are many alternative forms of IPO commonly employed by startups and startup promoters that do not include an exchange listing, so they may avoid certain regulatory compliances obligations, including mandatory periodic disclosures of financial information and factual discussion of business conditions by management that investors and potential investors routinely receive from registered public companies.

Investors are generally most attracted to those new companies distinguished by their strong co-founding team, a balanced “risk/ reward” profile (in which risk due to the untested, disruptive innovations is balanced out by high potential returns) and “scalability” (the likelihood that a startup can expand its operations by serving more markets or more customers). Attractive startups generally have lower “bootstrapping” (self-funding of startups by the founders) costs, higher risk, and higher risk, and higher potential return on investment. Successful startups are typically more scalable than an established business, in the sense that the startup has the potential to grow rapidly with a limited investment of capital, labour or land (Ghosh, 2014). Timing has often been the single most important factor for biggest startups successes, while at the same time it is identified to be one of the hardest things to master by many serial entrepreneurs and investors.

Startups have several options for funding. Revenue-based financing lenders can help startup companies by providing non-dilutive growth capital in exchange for a percentage of monthly revenue (Goodman, 2019). Venture capital firms and angel investors may help startup companies begin operations, exchanging seed money for an equity stake in the firm. Venture capitalists and angel investors provide financing

to a range of startups (a portfolio), with the expectation that a very small number of the startups will become viable and make money. In practice though, many startups are initially funded by the founders themselves using “bootstrapping”, in which loans or monetary gifts from friends and family are combined with savings and credit card debt to finance the venture. Factoring is another option, though it is not unique to startup. Other funding opportunities include various forms of crowd funding, for example equity crowd funding (Prentice, 2010), in which the startup seeks funding from a large number of individuals, typically by pitching their idea on the internet.

Necessity of Funding

While some would-be entrepreneurs believe that they cannot start a company without funding from VC, Angel, etc., Vwekwadhwa (2018) says that is not the case.

Startup Valuations

If a company's value is based on its technology, it is often equally important for the business owners to obtain intellectual property protection for their idea. The Economist (2005) estimated that up to 75 percent of the value of US public companies is now based on their intellectual property (up to 40 percent in 1980). Often, 100 percent a small startup company's value is based on its intellectual property. As such, it is important for technology – oriented startup companies to develop a social strategy for protecting their intellectual capital as early as possible (The Wall Street Journal, n.d). Startup companies, particularly those associated with new technology, sometimes produce huge returns to their creators and investors – a recent example of such is Google, whose creators became billionaires through their stock ownership and options.

Investing Rounds

When investing in a startup, there are different types of stages in which the investor can participate. The first round is called the seed round. The seed round generally is when the startup is still in the very early phase execution, when their product is in the prototype phase. At this level angel investors will be the ones participating. The next round is called Series A. At this point the company already has traction and may be making revenue. In Series A round venture capital firms will be participating alongside angels or super angel investors. The next rounds are Series B,C and D. These three rounds are the ones leading towards the IPO. Venture capital firms and private equity firms will be participating (Nasdaq, 2013).

Africa's Technology Startups and Investment

Of late, the expansion in the technology sector has witnessed a lot of startup investments in the African continent. In 2017, \$560million technology startup investments was said to have entered Africa. Out of the said amount, South Africa and Kenya got \$167.9million and \$147million respectively, while Nigeria earned \$114.6billion. the three countries accounted for 76 percent of the total funding that came into the region two years ago (Adepetun, 2018,p.33).

The Global System for Mobile telecommunications Association (GSMA), which revealed the figures at the 2018 Mobile 360 conference in Kigali, Rwanda, noted that lately, investors' attention is tilted towards countries including Ghana, Rwanda, Senegal and Uganda. This reason, according to GSMA, is

responsible for the cut in investment from 80 percent in 2015 and 2016 to 76 percent in 2017 in South Africa, Kenya and Nigeria. While Rwanda got \$36.7million, Ghana had \$20.4million, Uganda \$16million and Senegal \$10.7million funding in 2017.

GSMA said investment in the region's technology startup ecosystem is growing, adding that in 2017, 124 tech startups across Africa raised a total of \$560million, a 53 percent increase over the previous year. Of this amount, sub-Saharan Africa accounted for about \$515million in more than 100 deals. The range of tech startups funded and the growing size of deals reflect the accelerating development of the ecosystem. It explained that Fintech (21 percent), Solar (21 percent), e-commerce (19 percent) and edtech (12 percent) accounted for the highest shares of investment. This underscores the increasing innovation and investors interest in solutions that address the region's starkest social challenges, such as limited access to financial services, education and energy by large swathes of the population.

In October 2017, Uganda solar startup, SolarNow, secured a \$6million facility to help it reach more customers and expand access to pay-as-yougo (PAYG) solar power, GSMA stated that Kenya, Nigeria and South Africa remained the most popular investment destinations, accounting for 76 percent of total funds raised by startups in the region. However, the downward trend in the combined share of investments for the three markets, from more than 80 percent in 2015 and 2016, shows growing investor appetite for other markets, notably Ghana, Rwanda, Senegal and Uganda.

GSMA also revealed that in Africa, technology hubs increased from 89 in 2016 to 133 in 2018 in SSA. South Africa currently has 59 technology hubs, Nigeria 55, Kenya 30, Ghana 24, Uganda 16, Cote d'Ivoire 13, Zimbabwe 13 and Senegal 12. The body, which represents the interest of over 800 operators across the globe, said technology hubs are a critical part of the technology startup ecosystem, and they promote ideas and collaboration locally and provide startups with business support resources and services to help them scale.

In all of these, GSMA observed that SSA has a fast – growing technology startup ecosystem, which plays an increasingly important role in the development of home grown digital content and services. It stressed that mobile has remained a key factor in the region's startup ecosystem and that many technol-

Table 1. Showing African tech startups and funding levels according to regions

Region	Startup	Funding level	Specialization
North Africa	Shezlong (Egypt)	\$350,000 in 2018	e-health innovation
	Elves (Egypt)	\$2million at the close of 2017	machine learning and AI
	Halan (Egypt)	"multi million dollar"	Transportation
East Africa	Nala (Tanzania)	Not Available	Mobile money
	Taimba (Kenya)	\$19million	Agriculture
	UTU (Kenya)	\$250,000	Artificial intelligence
Southern Africa	Finchabot (South Africa)	\$563,000	ChatBots for financial service providers
	Appy Saude (Angola)	Not Available	Health care
	Vizibiliti Insight (South Africa)	Not Available	Artificial intelligence
West Africa	Cowrywise (Nigeria)	\$120,000	Automated service that helps users save money
	CowTribe (Ghana)	\$300,000	Animal vaccines
	KudiGo (Ghana)	\$300,000	Consumer retail industry

Source: www.disrupt-africa.com

ogy startups now use the technology as the primary platform to create solutions that address various socio-economic challenges.

Disrupt Africa has identified some outstanding startups to watch in 2019 and beyond, and their funding levels. They are presented in the table below.

Mobile Technology, Research and Development, and Africa's Technology Startups

The boom in startups has been aided by the growth in mobile technology. One of the key trends having a significant impact on how people engage with the world around them is the mobile device. Mobile phone penetration is forecast to exceed the 100 percent mark as early as 2021 – indicating that the technology will be a platform that should be focused on given the ease of access (Adepetun, 2019)

The growing uptake in mobile technology has aided many of the innovative digital solutions and services emerging from the continent, and, as mobile infrastructure advances and the cost of smart devices falls, technology entrepreneurs are developing uniquely African technology solutions to African problems. There are, however, natural challenges to still overcome such as lack of capital flowing into the sector. Africa's technology future is bright, but as the technology scene continues to flourish, entrepreneurs will need to be ambitious if they hope to compete on the global technology stage. One key method to achieve meaningful progress would be for governments in the continent to boost investment in research and development (R&D).

Investment in R&D has played a crucial role in the evolution of the technology spaces in Israel and Singapore. Although R&D spend does not usually bring immediate returns to the investors, the long-term benefits far outweigh any expenditure. In Africa, budgets are often stretched, with funding being directed towards more pressing needs such as healthcare and education.

Chika Nwobi, co-founder of Lagos-based Level 5 Lab (L5Lab) says:

I think that we are being unambitious about what we can do in the technology space. When you are very far behind in a race then you have to run faster just to catch the others. And investing more of our GDP in R&D is the only way Africa can reach and surpass the other (more developed) countries. R&D is like acceleration, so the most advanced countries (in the tech sector) are also the same ones that are spending the most on R&D, even though they are further ahead than (African countries). This is money that you spend, which might not have immediate returns, but it will help you leapfrog your development (Essiet, 2019,p.35)

The African Union has set a target for member states to spend at least 1 percent of GDP on R&D. According to UNESCO data, only Kenya, Mali and South Africa are close to achieving the target, and the latter is the only country that spends a significant proportion in the business sector. In comparison, Israel and Singapore spend over 2 percent of GDP, with Israel investing over 4 percent. Both nations have reaped the rewards of their investments, especially in the ICT sector (Africa Business, 2017, p.17).

In the meantime, the focus of the sector should be on skilling up young Africans so that they will be able to participate actively in shaping the global economy of the future. Nwobi advises

We all know that we are living in the digital age and there is a huge deficit of jobs in Africa, and Nigeria has huge youth unemployment issues. .so I believe that if we are to be prepared for the coming age then we need to educate an army of coders to take us into it. (African Business, 2017,p.17).

Theoretical Underpinning

This article is predicated on the technological determinism theory and the stakeholder theory. The technological determinism theory posits that technology shapes how we as individuals in a society think, feel, act and how society operates as we move from one technological age to another.

Most interpretations of technological determinism share two general ideas namely: that the development of technology itself follows a predictable, traceable path largely beyond cultural and political influence, and that technology in turn has effects on societies that are inherent, rather than socially conditioned or that the society organizes itself in such a way to support and further develop a technology once it has been introduced.

Croteau and Hoynes (2003, pp.305-307) define technological determinism as the approach that identifies technology, or technological advances, as the central causal element in processes of social change. They further asserted that as a technology is stabilized, its design tends to dictate users' behaviours, consequently diminishing human agency.

Fischer (1992) cited in Croteau & Hoynes (2003) characterized the most prominent forms of technological determinism as “billiard ball” approaches, in which technology is seen as external force introduced into a social situation, producing a series of ricochet effects. Postman (1992, pp.3-20) notes that the uses made of technology are largely determined by the structure of the technology itself, that is, that its functions follows from its form.

The core idea of stakeholder theory is that organizations that manage their stakeholder relationship perform better than organizations that do not. Freeman (2010, 1984) suggests that organizations should develop certain stakeholder competencies. These include:

1. Making a commitment to monitor stakeholder interests.
2. Developing strategies to effectively deal with stakeholders and their concerns.
3. Dividing and categorizing interests into manageable segments.
4. Ensuring that organizational functions address the needs of stakeholders.

FOCUS OF THE ARTICLE

Issues

The funding for African technology sector seems to be soaring and technology hubs are springing up rapidly, but the figures tell only part of the story. While the number of African startups raising funding at “series A” has been on the rise, the average investment amount in Africa at seed – stage is \$200,000, according to the pan-African venture capital community VC4Africa. This compares unfavourable to an average seed investment of \$1.14m in the US. Seed funding is the initial investment used when starting a business in exchange for equity.

Thomas Van Halen, research lead at the private equity firm Venture Capital for Africa (VC4Africa) said:

We still see that there is plenty of early stage money in the market. So the deals at the lower end are still happening on a large scale, but the follow-up money that goes into Series A, for example, is where we need new vehicles to increase investment at the next level (Essiet, 2019,p.35)

The relative dearth of funding available for African startups trying to scale up has been a major challenge for those companies looking to grow beyond their local markets. One of the primary turn-offs for international investors looking at the African-tech ecosystem is the lack of significant “exits”, according to Femi Longe, co-founder of Co-creation Hub (CcHub).

The main challenge in terms of getting funding is exit and there aren't that many success stories. If you look at the UK, for example, Facebook and Google are buying startups left, right and centre. So there is a possibility for an investor to see an exit because one of those big companies could buy them out. But in Africa, we only have a few examples of this (African Business 2017).

He said to boost the number of exits large local companies and startups should collaborate more often in mutually beneficial arrangements, where the corporation offers financial support and mentoring while the startup provides a solution that the larger organization does not provide. So the natural progression will go from collaboration to acquisition.

The model outlined by Longe is currently the most viable option for startups because African stock exchange tend not to hold enough liquidity for exits via an initial public offering (IPO). Some analysts believe that one of the primary reasons huge exits do not occur on a regular basis in Africa could be that most startups have focused on solving local issues rather than setting out to tackle global ones.

The rapid growth of the African technology sector was due mainly to the expansion of mobile technology and driven entrepreneurs seeking to find answers to some of the main challenges facing the continent. In the three key technology ecosystems of Kenya, Nigeria and, to a lesser extent South Africa, innovation has been fuelled by necessity.

In Kenya, Safaricom's M-Pesa, the mobile money platform which has around 19m active users in the East African country, was launched in 2007 as a way to offer financial services to low-income under banked Kenyans. At the time of the platforms launch, only 18.9 percent of Kenyans used traditional banking services. M-pesa provided a unique solution to a common problem in Africa by utilizing already existing technology, in this case, mobile to resolve an issue.

The technology scene across the continent is filled with examples of technology companies and entrepreneurs finding a gap in the market and plugging it with simple technology solutions, according to Iyin Adogbeji, co-founder of Andela and creator of digital payment service Flutterwave.

Because we have weak institutions and poor service delivery in Africa that have millions of people on the fringes, (tech companies) actually have the ability to reinvent society around infrastructure that is built with technology. The continent is undergoing a massive digital transformation. Every industry is digitizing, from banking to telecoms, and right at the centre of that are technology developers who are building applications that fit into that mission and supporting business to digitize their processes (African Business, 2017).

In Nigeria, where Aboyeji hails from, there are numerous examples of technology companies engaging in such activities, such as the online payment service Paystack and the e-health app Lifeback. While the technology innovations in Kenya and Nigeria have an obvious value in their home nations, overseas

investors still view startups in these markets as only dealing with African issues which do not translate to the global market, according to Paul Gabriel, Africa Analyst at Control Risks.

If you look at the solutions that the startups in Africa are developing, they usually are local in nature with unclear path as to how they can properly scale up. And where there is an overlap with other regions, such as the mobility sector, then the likes of Uber move in quickly and push out the local business (African Business, 2017).

However, the technology sector in South Africa, led by startups in Johannesburg and Cape Town, remains the most advanced on the continent, with the number of exits increasing year – on – year in 2016, and startups such as WhereIs, My Transport and website builder VIGO expanding to the UK and Asian markets, respectively.

Despite the positive indicators, Overseas investors, who are key to boosting the funding available for startups, prefer to err on the side of caution when investing in Africa. This could be as result of them showing lack of imagination or an understanding of the local market. As the technology scene in Africa continues to flourish, entrepreneurs will need to be ambitious if they hope to compete on the global technology stage. One tried and tested method would be for government to boost investment in research and development (R&D).

Problems

There is no doubt that Africa's startup scene is buzzing and the future for startups in the continent is promising because the world is fast becoming technology driven. Evidence has shown that strong economies are propelled by technologies and these technologies are in turn driven by startups, who have solutions that can support economy and business.

In the last couple of years, dozens of tech hubs, “accelerators” and “incubators” have sprung up across the continent. So trendy are African startups that even Silicon Valley has taken notice of the exponential growth. In August 2016, Facebook's Mark Zuckerberg visited Nigeria and Kenya, his first time on the continent in what is seen as a watershed moment for tech in Africa. In his wake US investors have warmed to the idea of deploying capital in Africa. It has also acted as a catalyst, armed with their iPads, laptops and innovating thinking, eager to tap into this emerging opportunity.

The buzz is palpable, but amid the hype it is not obvious how much impact this is having. The space is dominated by internationally backed startups like Nigeria – based – e-commerce firm Jumia, as well as global market entrants like Uber and Airbnb. Local markets remain fragmented, awash with small-scale and largely unprofitable startups. It is also dominated by just a few cities, with the vast majority of activity concentrated in Lagos, Nairobi and Cape Town where human resource and facilities are readily available.

Funding levels in Africa are trivial when compared to other regions. Available data shows that African startups – that is across all 54 countries – raised \$129m. China alone attracted \$31bn in venture capital for the same year, with the US receiving \$69.1bn.

Would-be tech entrepreneurs also have to contend with operating in the world's least entrepreneur – friendly environment. The Global Entrepreneurship Index lists 14 “pillars” of success including education levels, governance, economic complexity and depth of capital markets. The odds of success as an entrepreneur are correlated to ones country level of development. African nations cluster towards the bottom of the 137 – country index. Nigeria and Kenya, widely considered to be the driving forces

behind tech entrepreneurship on the continent, come in at 100 and 107 respectively. The startup scene is reminiscent of the largely defunct “Africa Rising” narrative of recent years, which focused on handsome GDP growth while ignoring a lack of structural transformation taking place on the continent.

Solutions

In view of the crucial role startups play in the development of business and society, the following solutions have become necessary.

1. African governments should provide enabling environment for technology startups to thrive in the continent. This should include providing interest free loans to help young entrepreneurs develop their business, and granting them tax waivers in the first ten years of operation.
2. Software solutions that would help solve problems locally in the continent should be developed by technology entrepreneurs.
3. There is need to establish more technology hubs in cities and rural areas across countries in the continent to assist young startups with internet access and free training.
4. Technology startups developers should look beyond the African market to get support. They should link up with foreign investors that would help them gain entrance into new markets in Latin America, Central, Eastern Europe and Asia to widen the net of African technology ecosystem.
5. Foreign entrepreneurs should be encouraged to organize more programmes geared towards providing learning curve and mentorship for startups in the continent in order to boost their growth rate and raise their standards in line with global best practices.
6. in order foster a healthy innovation eco system that drives economic growth and societal development, governments across the continent should provide old and up coming start ups with the latest equipment to ease their operations.

RECOMMENDATIONS

1. African governments should either provide funding or collaborate with private entrepreneurs to sponsor old and new startups developers in the continent.
2. Governments in the continent should provide a level playing ground for the development of infrastructure in both rural and urban areas that would support the growth of technology startups.
3. Startups need bandwidth to drive innovations. Since internet and broadband penetrations are still very low in the continent, governments should come up with the enabling infrastructure to ensure that these bandwidths are accessible to startups at reduced price.
4. African startups require funds for research and development to raise their quality to global standards in order to attract foreign investors. African governments should therefore provide assistance in this direction.

FUTURE RESEARCH DIRECTIONS

In recent years and up till now, the African technology sector has witnessed tremendous growth. This remarkable progress has attracted the world's attention, but fragmented markets, lack of funding and

unfriendly business environments pose problems for the continent's new entrepreneurs. For the continent technology startups to sustain its present growth and overcome the challenges, it requires the collaborative effort of the key stakeholders in the sector.

A stakeholder is a party that has an interest in a company and can either affect or be affected by the business. The primary stakeholders in a typical corporation are its investors, employees, customers and suppliers. However, the modern theory of the idea goes beyond the original notion to include additional stakeholders such as a community, government or trade association (Carroll & Buchholtz, 2014). Stakeholders can be internal or external. Internal stakeholders are people whose interest in a company comes through a direct relationship, such as employment, ownership or environment. External stakeholders are those people who do not directly work with a company but are affected in some way by the actions and outcomes of said business. Suppliers, creditors and public groups are all considered external stakeholders (Donaldson & Preston, 1995; Investopedia, 2018; Friedman & Miles, 2002; Friedman & Miler, 2006).

Florea & Florea (2013, p.132) aver that key stakeholders are important because of participation in the organization management and secondly, during decision – making process and implementation. The key stakeholders include policy makers, officials, important professionals or community personalities who have strong position or influence.

As African governments intensify their collaboration with technology startup founders and developers, there would be need to monitor the progress made in individual countries across the continent. How far they are able to surmount the challenges and scale-up the sector to meet global standards will likely form the core of future research in this domain.

CONCLUSION

Africa's technology sector is undergoing a massive revolution. This is evident in the introduction of new and relevant startups and technology hubs across the continent, and these are making a difference in the economy of some African nations. The rise in the number of startups and technology hubs is an indication of how resilient the technology ecosystem in Africa has been. As funding for the sector soars and technology hubs spring up rapidly, African startups are attracting the world's attention.

KEY TERMS AND DEFINITIONS

Business Environment: Is the combination of internal and external factors that influence a company's operating situation. It can include factors such as clients and suppliers; its competition and owners; improvements in technology, laws, and government activities; and market, social, and economic trends.

Digital Transformation: The process of using digital technologies to make a process to become more efficient or effective.

Entrepreneur: Is an individual who, rather than working as an employee, funds and runs a small business, assuming all the risks and rewards of the venture.

Fragmented Market: Is a marketplace where no single organization has enough influence to move the industry in a single direction. The market consists of several small to medium-sized companies that compete with each other and large enterprises.

Funding: Is the act of providing financial resources, usually in the form of money to finance a need, programme, and project by an organization or company.

Innovation: Is the process of creating value by applying novel solution to meaningful problems.

Investor: Is a person or other entity who commits capital with the expectation of receiving financial returns.

Startup: Is a newly established business venture that aims to develop viable business model to meet a marketplace need or problem. It is usually small and initially finance and operated by an individual or a handful of founders.

Scale-Up: A business that is in the process of expanding.

Tech Hub: Is a physical space—a city, a suburb, or just a suite of offices—which has developed to help technology startup companies succeed.

Knowledge in Science and Technology Parks

INTRODUCTION

Science and technology parks (STPs) are considered as a kind of public-private partnerships designed to increase regional wealth and to foster technology start-ups growth in developed and/or in developing regions (Martínez-Cañas et al., 2011). The main aim of these institutions is to reproduce the successful factors of regional phenomena such as Silicon Valley or Boston's Route 128 (Mian et al., 2016). These institutions are focused on fostering knowledge flows, mainly among tenant institutions, as well as between tenants and nearby external institutions. Although there is no official definition of STPs, some common denominators across different existing models suggest a set of minimum standards and requirements that any knowledge cluster should have to earn this formal recognition (Link, 2009). According to the International Association of Science Parks (IASP, 2002), a science park is "*a public or private organization managed by specialized professionals, whose main aim is to increase the wealth of its community by promoting the culture of innovation and the competitiveness of its associated businesses and knowledge-based institutions*".

Among the common denominators of STPs we can highlight the agglomeration and promotion of interactions among R&D centers, Labs, entrepreneurs, Universities, specialized human capital, innovation infrastructures, venture capitalists, research consortia, research projects, technological capital, and social capital (European Commission 2008). These factors are related and favor the capacity of any firm or institution to adapt constantly to technological, economic, and social changes in markets (Albahari et al., 2016). Therefore, STPs have emerged based on new institutional and artificial arrangements that facilitate interactive relations and knowledge exchange among three main groups of agents: Universities-R&D Centers, industry and government research agencies (Etzkowitz, 2008).

To enable these goals to be met, a Science Park aims to stimulate and manage the flow of knowledge and technology amongst universities, R&D institutions, companies, and agent's markets; it also facilitates the creation and growth of innovation-based companies through incubation and spin-off processes; and it even provides other value-added services together with high-quality space and facilities (Mian et al, 2016).

The main objective of this chapter is to shed some light in the role of STPs as specialized institutions leveraging knowledge creation and diffusion. First, the origin and evolution are analyzed. Second, the evolution and typology of models of STPs are showed. Finally, conclusions and future research directions will be proposed.

DOI: 10.4018/978-1-7998-3473-1.ch109

BACKGROUND

9

STPs were originated in the United States as industrial concentrations that were quickly copied by other regions (Castells and Hall, 1994). The idea of concentrating companies in one single area became increasingly important in the mid-20th century, particularly during the World War II (Zhang, 2005). Shortly after that, most innovative companies were aware that science had made a vital contribution to victory (atomic energy, radar, aeronautical developments, etc.) and decided to develop an approximation to leading universities. This is how the first science parks came about around Stanford University and Menlo Park in California, both created towards 1950 (Hansson et al., 2005). In Europe, this phenomenon was retarded for almost twenty years. In the late 1960s, some universities in the UK, such as Cranfield and Cambridge, took action along these lines. In the first years, the growth and impact of parks were weak. Nevertheless, in the 1980s, the British government asked universities to be more collaborative with industry (Allen, 2007). This pressure led to the second wave of parks promoted by the main British universities. Growth continued during the 1990s and by then, more than half the universities already had some kind of agreement or collaboration with science parks. In France, the most significant example is Sofia-Antipolis, created around 1970. The first parks in Italy and Germany started in the early 1980s, concretely the Area Science Park in Trieste and the Technologic Park in Heidelberg, respectively. In Spain, the first park was not created until the second half of the 1980s. The first initiative was the Zamudio Technology Park (Bilbao), created in 1985. In summary, the creation of STPs throughout Europe and the United States has spread to other countries and continents and is currently considered a global phenomenon. Nowadays, there are hundreds of Science Parks and areas of innovation worldwide.

Studies and research on STPs are in an emerging stage of development, and during recent years researchers have stimulated an important academic debate concerning whether such property-based initiatives really enhance the performance of firms and economic growth of regions (Martinez-Cañás et al. 2011). To this respect, there are differences of results in previous empirical research with findings that show positive or no-significant effects of STPs on the firms' performance (Link 2009). This divergence implies that previous studies do not analyze STPs from the point of view of their active role in the knowledge-based economy where intangible and relational aspects are critical in the market (Hansson 2007).

The research in STPs can be divided into two distinct, but complementary, aspects of STPs and areas of innovation: First, on the one hand, there is research concerning the effective role that STPs have as infrastructure. That is, they play an important role as a highly specialized institutions (with a mix of public-private policies, quality space, incubation facilities, spin-off mechanisms, the ability to accelerating the growth of small-medium firms and high value-added services) that are artificially created to help develop their environment economically. On the other hand, they also play an important role through favoring a dynamic and innovative stimulation and management of the flow of knowledge and technology between universities and companies. That is, STPS facilitate the communication between companies, entrepreneurs, and technicians, providing environments that enhance a culture of innovation, creativity, and quality, for companies, research institutions and on people: the entrepreneurs and 'knowledge workers'. The prominence of this second aspect is being powered by the work of the IASP with a global network that gathers many thousands of innovative companies and research institutions across the globe, facilitating the internationalization of their resident companies.

ISSUES, CONTROVERSIES AND PROBLEMS

Research in Science and Technology Parks show several issues, controversies and problems. Here are highlighted the most important issues:

Firstly, Science and Technology Parks as platforms that enable tenant firms to innovate thanks to their networking nature across universities, research labs, start-ups, SMEs, and large firms. However and according to Simsek and Yildirim (2016) their innovative context have several factors that obstruct innovation. Their research found important constraints concerning “confidentiality and conservativeness of the firm” (not all firms want to share their knowledge and patents), “human resources, brand and image” (people flow from firm to firm forgetting loyalty and spreading firm best keep secrets), “resources and costs” (being located inside a science park is not cheap and some resources are outside their limits), “management and organization” (some parks don’t promote networking activities and only are offering administrative help), “market, partnership, and technology sources” (in order to gain benefits from innovation is needed to create partnerships with competitors) and “administration” (to create value administration has to offer high quality services and overall promote networking). Therefore, located firms should face some issues in order to obtain benefits for their location and activities inside the infrastructure.

A second issue is related to the effectiveness of Science and Technology Parks as instrument of innovation policy. Accordingly, there is a gap in the existing literature on STPs because mainstream research mostly does not consider STPs’ heterogeneity. In a recent paper by Albahari et al. (2016) they study the influence of different STP characteristics on their tenants’ performance founding that firms located in very new or longer established STPs show better innovative performance. Also Albahari et al. (2016) found that the size of the STP and its management company positively affects the innovative performance of tenants while services provision has no effect on firms’ achieving better results. Furthermore, they found that firms in less technologically developed regions benefit more from location in an STP.

And finally in third position, another important issue is related with process effectiveness. Seems clear that located firms need an important acquisition capacity to acquire and assimilate the knowledge provided by universities, mainly due to being academic spin-offs or having long-term relationships with them. A recent study made by Díaz-Vial and Montoro-Sánchez (2016) argue that firms located in central positions of the firms network inside the STP have access to a complementary source of technical knowledge. Also they found that having long-term relationships with universities, based on both formal and informal interactions, is the most important means of obtaining technical knowledge from them. Díaz-Vial and Montoro-Sánchez (2016) also observed a positive relationship between the technological knowledge obtained from universities and the innovation carried out by firms. Consequently, it is showed the significant role of go-betweens in order to gain a high level of innovation.

SOLUTIONS AND RECOMENDATIONS

Solutions and recommendations for issues analyzed in the previous section of this chapter are mainly related with economic regions policies for developing Science and Technology Parks. However, and despite of decades of progress and experience, politicians have realice that Science and Technology Parks are a complex and multi-faceted phenomeno because many gaps and unanswered questions regarding the incubation process remain. Mian et al. (2016) in a recent article published where they made a state of art proposing some solutions and recommendations in order to advance in the knowledge about STPs:

- Still is needed an integrated definition of STP, because there are a lot of elements that need to be included in, such as: physical space, professional management, entry and exit policy, a mix of business support and professional services, networking, access to capital, and university resources among others.
- It lacks of a unified theory about what really incubation is and which value-added processes are included. Consequently, a contingency approach to incubation should be proposed to address varying objectives, organizational form, and context.
- The role of public support must be defined by emphasizing how societal objectives and social returns of innovation exceed the private returns of these activities. Therefore it needs to be studied how providing indemnification of the entrepreneur's risk by supporting an embryonic technology that may not emerge otherwise.
- Despite the general acknowledgement that STP phenomenon is related with integration of activities and value-added infrastructure, a nested a dynamic and multidimensional view of STPs is needed. Mainly because there are a lot of bridging mechanisms embedded within a dynamic innovation ecosystem that need to be explored with different levels of analyses-national, regional/state, park/incubator, and entrepreneur/team level (Etzkowitz, 2008).
- Another important issue to be solved is mechanism's governance because of relationships between management, client firms, and other key stakeholders. For example, university incubation programs need to address the STP role in bridging entrepreneurial firm-university relations (Díez-Vial and Montoro-Sánchez, 2016. Also and at a more micro level an in-depth exploration of the incubation process is still needed (Ahmad, 2014).
- The last recommendation is related with the analysis of accelerators and firm assistance over a limited period to help young TBFs achieve sustained growth. Incubators powered by accelerator can be an essential tool for successful STPs.

FUTURE RESEARCH DIRECTIONS: EVOLUTION OF STPs MODELS

STPs models are as diverse as individual initiatives have been carried out (European Commission, 2008). In any case, they all are characterized by the fact of being public-private organizations “managed by specialized professionals”. Their main aim is to increase the wealth of its region/community by promoting the culture of innovation and the competitiveness of its associated businesses and knowledge-based institutions. The difference among one type of STP and another is the nature of stimulation of the flow of knowledge and technology amongst universities, R&D institutions, companies, and markets. Furthermore, there are notable differences among the intentions of the promoters and the selected place for a physical location, which can influence on the creation and growth of innovation-based companies through incubation and spin-off processes; and can provide other value-added services together with high-quality space and facilities (IASP, 2002).

In practice, there are different models of Science Parks and Research Parks. While the former denomination is the most common in Europe, the latter is widely used in the United States and Canada (Sanz, 2003). Furthermore, Science parks in Europe coexist with technology parks.; there are not great differences between both concepts. The main differences probably refer to the size or the possible admission of productive activity. While a science park is of reduced size, with strong links to university and little emphasis on manufacturing activities, a technology park is medium-sized or big and allows for productive activities (IASP, 2002).

From a geographical point of view, science parks are mainly located in the United Kingdom (British model), while technology parks refer to the «Mediterranean model», which is typical of countries like France, Spain, Italy, and Portugal. Apart from these two best-known models, there are other similar concepts like Technopole, Business Park, Innovation Center, Science City and living lab (please see complete definitions in the last part of the chapter).

Despite the wide typology of Science Parks and areas of innovation, a holistic point of view about their nature, promoters, governance systems, and innovation policies is really needed. According to Annerstedt (2006) and Haselmayer (2004), we can find up to three generations or models of STPs and areas of innovation (see Table 1):

Table 1. Models of STPs development

	1 st generation STPs	2 nd generation STPs	3 rd generation STPs
Nature	Science push	Market pull	Interactive
Main promoter	Government/Region /Universities	Business located in High-Tech zone or Tecnopoles	Government, University & Industry in an urban location
Governance	A foundation or a limited company created by a University	A privately-owned company that manages the park	Strategic decisions (owners) and day-to-day decisions (a highly specialized company)
Innovation	Linear system (from science to business)	The first phase of innovation (Raw innovation)	Interactive innovation (push and pull) oriented to the last phase of the innovation process

Source: Adapted from Martinez-Cañas and Ruiz-Palomino (2011)

- First Generation STPs, are an extension of a university into a dedicated neighborhood area that includes incubating facilities for start-up firms, related business services and, as importantly, includes pathways into new, research-based technology (and know-how) for potential investors and other business entities. The typical mode of governance of a First Generation Science park is that of university-control through a foundation or limited company, created by the university or a related association. The innovation philosophy of a First Generation Science park is a “linear approach” to innovation, which sees scientific results as raw material for innovative activities. That is, in these types or generation of STPs, knowledge flows from universities and research centers to firms.
- Second Generation STPs are mainly science-economy interaction institutions. They are also considered as an extension of a university (or other major R&D facilities) into a dedicated high-tech zone. Managers respond to the businesses needs included in the STP by favouring a mix of high-quality facilities into the Park. The typical mode of governance of a Second Generation Science park is that of a privately-owned company which manages the Park. Academic or other research representatives must be involved with local or regional policymakers. The innovation philosophy of a Second Generation Science Park is “demand pull” where research results and techno-scientific findings are regarded as “raw materials” for the Park’s innovating firms. In this model, tenant firms establish in the park and create agreements with research institutions in order to obtain applied knowledge that can be exploited as innovations in the market.
- Third Generation STPs are the new model among the current evolution of STPs. Generally, these STPs are located within a vibrant urban community and are perceived as the quintessence of

science-industry-government relations, increasingly functional and specialized along with its participation in local, regional and even global innovation activities. The objective in these STPs is to increase the wealth of the whole community that the Park serves by promoting science-industry-government relations in a number of ways. The typical mode of governance is through long-term public-private partnerships, where strategic decisions regarding the Park's operations are agreed through joint decisions, while the day-to-day operations can be carried out by a highly-specialized limited company. The innovation philosophy is cluster-oriented "interactive innovation". It is both "science push" and "market-pull". In this model, knowledge is created through an interactive process where value co-creation is the rule. Customers, research institutions and firms are together co-creating knowledge and innovating.

Therefore, the evolution of these infrastructures has created a new emerging model of STP that operates through interactive models of innovation, and that is embedded in diverse urban environments. In such areas, networks and systems of trust, the development of respective public, private or scientific partners, cultures of interpretation, and degrees of public or institutional participation, as well as the availability of financial/legal instruments all, form an integral part of the innovation environment's global function (Annerstedt, 2006). Location embeddings is no longer just a feature, but a key success factor (Haselmeyer 2004).

Other key success factors and best practices that this third generation STPs must take care are also considered by John Allen report at Manchester Business School (2007):

- Born as a global project to overcome a limited regional or local scope.
- Being part of a sustainable community and being a sustainable business.
- Having a long-term strategy with clear objectives.
- Being a gateway to innovation and not a destination.
- Being managed to optimize serendipity.
- Being developed to aid creativity, interaction, and innovation.
- Growing a strong two-way relationship with the associated university.
- Building active networks of all kinds and at all levels.
- Establishing an understanding of each tenant's needs.
- Offering incubation facilities either directly or indirectly.

Research on STPs was primarily concerned with comparing the benefits of tenant and no-tenant firms (Hansson, 2007). However, located firms base their competitive advantage largely on their technological resources and innovation capabilities in order to create and leverage knowledge. Therefore, knowledge helps in the process of developing the innovation capacity directed to the launch of new products and/or services. This innovation capacity could be internally developed by relying on internal R&D; however, it can also be externally acquired by buying it in the market or, more importantly, by establishing technological collaborations with other R&D partners located inside or outside of the park. Consequently, this technological collaboration provides participating firms with opportunities to acquire technological resources and capabilities such as capital, knowledge, innovation, and consultancy in the field of high technology (Löfsten and Lindelöf, 2005), and enable them to share complementary resources with other firms.

Science Parks act as a catalyst fostering agreements and improving the innovation performance derived from technological collaboration between firms and research and technology organizations (Martinez-

Cañas et al. 2011). The geographical proximity of these agglomerations provides opportunities for formal and informal contacts as well as strong links which allow knowledge exchange (Bakouros et al. 2002) and may lead to joint projects developments among their tenants (Fukugawa 2006) through which to gain access to mutual exchanges of resources, information and knowledge (Siegel et al, 2003). Accordingly, the success of technological collaboration and knowledge exchange depends on the creation of a favorable innovation environment. Science Parks provide located firms with a more appropriate technological environment than is available to firms in off-park locations, encouraging them to establish their technological collaborations and stimulating research productivity among on-park firms (Siegel et al. 2003).

Moreover, technological knowledge flows more easily locally than over great distances, favoring the generation of more knowledge spillovers which on-park firms can transform into valuable new products, services or processes (Löfsten and Lindelöf, 2005). Additionally, Science Parks offer firms several general and specialized services such as financial and marketing support to help them succeed in the commercialization of their new products (Martinez-Cañas et al. 2011). In summary, because of the important role of STPs in helping firms develop and improve their competitiveness, further research on Science Parks is needed. In particular, more studies are needed that investigate and advance our understanding concerning intangible aspects such as knowledge creation, knowledge acquisition, knowledge implementation, technology diffusion, social capital, trust, reputation, talent retention, projected image, employer branding and people management in knowledge institutions among others lines of research.

CONCLUSION

Science and technology parks are catalytic institutions designed for creating and fostering new environments favorable to innovation. Thus, the main contribution of this chapter has been to focus on analyzing the knowledge and innovations generated through relations fostered with effective networking activities to encourage the transfer of knowledge, resources, and innovations from universities and research institutions located inside.

The world has seen an increasing number of science parks since the 1960s, but still lacks systematized accumulated knowledge about science parks. The current chapter has briefly tried to analyze and evaluate the science park phenomena.

STPs are the result of a deliberate action amidst many taken within a given environment to compete in the knowledge economy. This concept is closely related to concepts such as science cities and knowledge regions and their goal is to consolidate areas competing based on paradigms related to the new economy. All agents in this geographical area should act in a coordinated way and with a wide range of simultaneous actions.

In conclusion, the knowledge environment of STPs must be oriented towards interactivity of agents:

- In the global economy, STPs should move towards a wider environment than their own borders, a very appropriate strategy for regions wishing to change their competitiveness in order to be a worldwide reference region.
- Parks should differentiate and specialize in their activities searching for better identification of its personality, brand and projected image.
- Parks needs to define its main priority, related to the creation of a scientific climate or a market climate for creating new knowledge-based companies. Also, a STP can combine both concepts and follow them simultaneously, but the focus needs to be fully justified.

- Facilities and buildings are not the key elements. Although they represent a necessary variable, STPs should give even less importance to the physical space and give more importance to synergies, the diversity of centers and value-added services instead.
- The role of universities and other research centers should focus on creation and spillover of intangible resources.
- Capturing and involving non technology-related sectors such as the real estate sector that should be attracted by future profits.
- STPs management is critical in its initial stages, and it should be professional driven.

KEY TERMS AND DEFINITIONS

Area of Innovation: They are places created and designed to attract entrepreneurial-minded people, skilled talent, knowledge-intensive businesses, and investments, by developing and combining a set of infrastructural, institutional, scientific, technological, educational and social assets, together with value-added services, thus enhancing sustainable economic development and prosperity with and for the community (IASP, 2002).

Business Park: It is an area that is specially designed to have business offices, small factories, etc. Sometimes it is just a for renting spaces, with no other value-added services.

Industrial Cluster: Clusters are groups and networks of interdependent firms, knowledge-producing institutions (universities, research institutes, technology-providing firms), bridging institutions (e.g. providers of technical or consultancy services) and customers, linked in a production chain which creates added value together. The concept of the cluster goes beyond that of firm networking, as it captures all forms of knowledge sharing and exchange. Clusters have a more industrial or productive orientation than science and technology parks.

Innovation Center: It is a space where organizations of any kind establish labs or spaces for makers (makerspaces) on their own campuses. Oftentimes, corporations use an innovation center to showcase their own innovations or new products to employees, investors or even customers. And, as spaces for innovation, innovation centers typically include the latest technologies and tools for employees to use to experiment or iterate on their ideas or see how else they might apply the technologies in their businesses. An innovation center also serves as a space where people can gather and where design thinking for innovation can directly happen, meaning it is designed to host brainstorming sessions, design sprints, or innovation workshops.

Living Lab: A living lab is a research concept. A living lab is a user-centered, open-innovation ecosystem, often operating in a territorial context (e.g. city, agglomeration, region), that integrates concurrent research and innovation processes within a public-private-people partnership.

Research Park: It is an area where companies have offices and laboratories and where they do work involving science and technology. This is the most common denomination in the US. Mainly, Research Parks are promoted by private corporations.

Science City: A science city is an urban settlement endowed with developed (independent or shared with nearby cities) infrastructure, manufacturing and service sectors, and industrial facilities. Also is considered as a major scientific and technological complex, which is put in place primarily to address priorities of national defense. This factor underpins the creation of these infrastructures in countries such as Russia.

Science Park: A science park is a public or private organization managed by specialized professionals, whose main aim is to increase the wealth of its community by promoting the culture of innovation and the competitiveness of its associated businesses and knowledge-based institutions. This is the most

common denomination in Europe. Science Parks are mainly promoted by public institutions such as Universities and their size is smaller than areas of innovation and industrial clusters.

Technology Park: A landscaped development usually comprising of high specification office space as well as residential and retail developments, designed to encourage localization of high technology companies operating in related sectors such as information technology, software development, etc., thereby giving each the benefit of economies of scale and location.

Technopole: Technopole describes regions worldwide dedicated to technological innovation. Technopoles may be developed by the private sector or by the co-operation or partnership between the public and private sectors. Governments of all levels promote them as a panacea for economies hurt by economic restructuring. Large corporations and small business operate within these high technology areas. Networking between companies is important and made possible by technological advances. Technopoles are combined technological and business centers specifically established around recognized educational and research institutes.

INTRODUCTION

The globalization of markets and production has been sparked by pervasive technological change and led to the internationalization of many companies whether large, medium or small. As such, internationalization is ever present in basically all contemporary business activities as it is a dynamic process that is the result of the exploitation of competitive advantages (Stanisauskaite & Kock, 2016).

Business internationalization has evolved over time involving different theories and understandings (Ribau, Moreira, & Raposo, 2015). However, not only there is no single definition of internationalization but also there is a myriad of topics involved in the analysis of internationalization (Ribau, Moreira, & Raposo, 2018).

Internationalization refers to the process of increasing involvement in international activities and is related to how firms explore international markets (Moreira, 2009). Many studies analyze the internationalization process based on four main strands: the Uppsala model, that advocates an evolutionary, sequential and linear model of international involvement (Ribau, Moreira, & Raposo, 2015); the network-based view of the firm (Hakansson & Snehota, 2006), based on a relational-based perspective among market players; the eclectic paradigm that explains the main drivers of internationalization among firms based on three main specific advantages – *Ownership, Location and Internalization* (OLI) advantages (Dunning, 2000); and the theory of international entrepreneurship that advocates that firms seek to exploit their specific advantages in international markets based on the exploitation of their internal capabilities (McDougall & Oviatt, 2000).

The globalization of business and investment has led to the growth of the internationalization of tourism related activities, namely of hotel chains, as a means of diversifying their services, which began to

DOI: 10.4018/978-1-7998-3473-1.ch110

invest in new locations across the world. This is also the result of the exponential growth that tourism has been experiencing.

The theories of internationalization have dealt with an evolutionary perspective covering the macro/nation perspective and the industrial perspective, but have not fully disclosed the internationalization of service firms, especially from the hotel industry perspective (Ribau, Moreira, & Raposo, 2018).

There are different internationalization strategies between the business and tourism industries, since not only they have different activities but also different objectives, the tourism industry being more focused on service activities, which may influence the internationalization process (Berbel-Pineda & Ramírez-Hurtado, 2012; Marco-Lajara, Zaragoza-Sáez, Claver-Cortés, Úbeda-García, & García-Lillo, 2017). The internationalization of the hotel industry necessarily implies the presence and provision of services in foreign markets, which is quite unique in globalized industries (Berbel-Pineda & Ramírez-Hurtado, 2012; Marco-Lajara et al., 2017).

The mode of entry into foreign markets is considered to be one of the most critical strategic decisions that firms have to make, given the repercussions on business success (Young, Hamill, Wheeler, & Davis, 1989; Berbel-Pineda, Palacios-Florencio, & Ramírez-Hurtado, 2017).

In general, there are three main ways of serving foreign markets (Rothaermel, Kotha, & Steensma, 2006): exports, licenses and / or direct investment. Each option has different implications for the firm in terms of the level of control the parent company has over the foreign operations, the resources it must commit, and the potential benefits it can obtain (Buckley, 1995; Root, 1987). Considering the importance of the hotel industry as a result of the growing internationalization process, the objective of this chapter is to analyze the ways in which hotel chains internationalize and relate them to the main underlying theories of international business.

The chapter is structured in six sections. After the first section that presents the chapter the second section addresses literature on motivations for internationalization and modes of entry in international markets, namely in the hotel industry. The third section explores the main results found. The fourth section discusses the main results. Section five presents the main conclusions of the chapter. Finally, section six explores future research directions.

BACKGROUND

Internationalization Theories

There is no single definition regarding firms' internationalization, mainly due to the different theories and approaches used to explain internationalization (Ribau et al., 2015). The phenomenon of globalization of investment has led to the internationalization of tourist activities, including hotel chains which, as a way of diversifying their services, have begun to invest in new locations throughout the world. On the other hand, globalization has led to the exponential growth of tourism, which in turn has led tourist companies to invest in internationalization to take advantage of their intrinsic skills.

Although there are several theories that explain firms' internationalization, there are four main theories that have been widely used (Ribau et al., 2015), as referred to above: the Uppsala model, the Eclectic Paradigm, the network-based perspective and the theory of international entrepreneurship. However, they tend to ignore the internationalization of service-based firms, in general, and the internationalization of the hotel industry, in particular.

The Uppsala model defines internationalization as a gradual process with several sequential steps. It is a theory based on an evolutionary perspective in which the behavior of the firm is based on a knowledge-commitment binomial relationship in which firms increase their international reach and enter new markets as they know these markets (Ribau et al., 2015). According to Child, Rodrigues, and Frynas (2009), firms choose markets sequentially according to the perceived proximity to those markets, based on the low psychic distance, since as they manage to control the inherent risks of internationalization they incorporate basic knowledge to enter other foreign markets (Etemad, 2009).

The Eclectic Paradigm explains the causes of firms' internationalization through the specific advantages firms must master in order to be successful in the internationalization process. That is, to have their own skills or intangible assets and be able to provide these services internally and seize opportunities abroad in order to take advantage of their specific advantages.

According to Dunning (2000), this theory is predominant when talking about international business as it integrates economic theories, foreign direct investment (FDI) and international activities of multinational companies (MNCs). When using the eclectic paradigm it is necessary to follow a holistic perspective since the variables under consideration are interdependent (Dunning, 2000).

The theory of internationalization networks assumes that firms are interdependent and that their expansion abroad results from established relationships among previously interacting business units (Håkansson & Ford, 2002). Networks established in relationships with different stakeholders and shared resources support firms' internationalization process (Johanson & Mattsson, 2015). This is because firms are dependent on resources controlled by other parties, leading to the creation of relationships that represent the process of consumption of those goods (Ribau et al., 2015). As such, entering new countries gives companies the opportunity to create relationships that can help them reach new markets abroad. Moreover, these relationships are a potential competitive advantage for the internationalization of SMEs through the sharing of both information and knowledge (Ribau et al., 2015).

Internationalization of Service Companies

Regarding the classification of services, there are some important contributions that seek to explain how the different types of services are internationalized (Lovelock, 1996; Erramilli, 1990; Clark, Rajaratnam, & Smith, 1996). It is important to note that each typology has its direct influence on entry modes and integration strategies in international markets.

Lovelock and Yip (1996) classified services into three main types: people-processing services; possession-processing services; and information-based services.

People-processing services involve tangible actions in which the consumer becomes an integral part of the service production process, where production and consumption take place simultaneously. These types of services require that the consumer is present in the establishment of the service provider, or that the supplier directly provides the service to the consumer. In these cases the modes of entry in international markets should involve a local geographic presence. Possession-processing services involve tangible actions on physical objects, that is, objects are involved in the service production process. Geographic local presence makes sense when it is assumed that the service will be provided on a continuous basis. Finally, information-based services are related to the manipulation, collection, interpretation and transmission of data and knowledge (Lovelock & Yip, 1996).

Regarding the way services are internationalized, Clark, Rajaratnam, and Smith (1996) classified services into four different types: international contact-based services; international vehicle-based services; international asset-based services; and international object-based services.

International contact-based services are services in which the supplier maintains direct contact with the consumer, involving for example legal services, consulting services, or professional services. According to Javalgi, Griffith, and White (2003), this type of service has all the classic characteristics of services (intangibility, inseparability, perishability, and heterogeneity).

International vehicle-based services are those in which the supplier does not need to physically establish itself in other markets.

International asset-based services involve physical presence in other markets – such as banks or hotels – that represent the capabilities of the companies (countries) that export these services.

International object-based services are contact-based services that are embedded in physical objects.

Erramilli (1990) classified the services taking into account the required interaction between the service provider and the consumer, dividing it into hard services and soft services. The former are services in which the production and consumption process are separated, and that the need to be present during the provision of the service is limited or non-existent. On the other hand soft services require that the production and consumption occur simultaneously, as for example, catering services and health services.

When comparing Lovelock and Yip's (1996), Clark et al.'s (1996) and Erramilli's (1990) typologies, one can claim that people-processing services and soft services fit into the types of services that involve great interaction between the service provider and the consumer, whose production and consumption processes are inseparable.

Theoretical Challenges

It is important to note that hotels and hotel chains can expand through acquisitions, cooperation or partnerships, or even integrating certain brands into their own core brand, creating large international hotel chains that increase industry competition. Uppsala's model is not fully adapted to the different forms of investment that exist in the hotel industry as hotels and hotel chains seek to exploit international opportunities through modes of entry such as franchising or FDI at any given point in time without necessarily holding deep knowledge of market behavior or without following an evolutionary perspective. Moreover, over time, there is not necessarily a gradual growth or expansion in the destination market given the volatility of tourism markets, where some tourist destinations may experience uncontrollable swings due to variations of the external context.

In the case of the hotel industry, it involves other support services that are not directly related to the provision of accommodation. Thus, in the case of the eclectic paradigm, there are services that can be internalized by the company, although there are others that can be easily outsourced without jeopardizing the company. The locational advantages can be crucial for the internationalization of the hotel company or hotel chain, as long as it has an international image, reputation and brand. Nowadays, internalization can take place as a result of both high competitiveness among firms and the need to keep abreast of information so that companies can retain full proprietary advantages in order to exploit them more easily as a result of an ownership advantage. Taking these aspects into account, the eclectic paradigm could be clearly useful in explaining firms' internationalization in the tourism industry. Despite this, there are authors who consider that it is a theory that does not fully explain the internationalization of the hotel industry by not considering all the agents involved, such as other services, local authorities, financial companies, among others (Niewiadomski, 2014).

Some authors link the internationalization of the hotel industry to the Eclectic Paradigm (Chen & Dimou, 2005; Dunning & Kundu, 1995; Williams & Shaw, 2011). However, Chen and Dimou (2005) argue that large MNCs do not have a country of origin, especially when it refers to the hotel industry, since

some hotel chains change ownership/proprietorship several times leading to a change in the company's headquarters, culture and portfolio of activities, which ultimately influences the company's investment strategy and sites. In addition, in the hotel industry SMEs tend to adopt different internationalization strategies than those used by large multinationals, although over time, when smaller groups grow, these differences tend to disappear.

Internationalization in the Hotel Industry

The internationalization strategy varies according to the different activities companies carry out (Berbel-Pineda & Ramírez-Hurtado, 2012; Narula, 2012). Moreover, the vision and mission of each company also differs. The internationalization of the hotel industry necessarily implies a presence in foreign markets and the provision of local services, being one of the most globalized industries (Berbel-Pineda & Ramírez-Hurtado, 2012; Marco-Lajara et al., 2017).

The mode of entry into the foreign markets is considered one of the most critical strategic decisions that companies have to take, since it has repercussions on the success of the business (Young et al., 1989). In general, there are three ways to serve foreign markets: exports, licenses and / or direct investment (Rothaermel et al., 2006). Each of these options has different implications for the company in terms of the level of control the parent companies have over foreign operations, resources that they must provide, and potential benefits that they can obtain (Buckley, 1995; Root, 1987). However, entry modes need to be differentiated according to the level of control companies desire (Aliouche & Schlentrich, 2011; Haro, Gândara, Rastrollo, & Mondo, 2014; Pla-Barber, León-Darder, & Villar, 2011).

The main modes of entry in foreign markets implemented by hotel companies can be clustered in three main groups (Pla-Barber & León-Darder, 2004; Rodríguez, 2002):

- Direct investment modes with full control, which can include Greenfield investments or mergers with existing companies. A merger is an economic operation that brings together two or more companies giving rise to a new one, while an acquisition consists of the purchase of one company by another.
- Cooperative contracts that may involve Joint ventures (JVs) and/or international strategic alliances. These contracts allow companies to penetrate foreign markets, always maintaining some control over its administration. These processes involve direct investment with shared control over activities. These cooperative contracts allow companies to share resources, split risks and dissolve cooperation after project completion (Silva & Sousa, 2009).
- Franchising agreements and management contracts can also take place when companies wish to expand into the new market transferring certain advantages to a company located abroad.

These three modes of entry can be divided into two groups (Berbel-Pineda et al., 2017):

- Equity-based entry modes (FDI and JVs): with these modes, hotel chains commit more resources in their internationalization process, but also enjoy greater control over their foreign business operations.
- Non-equity entry modes (franchises and management contracts). Through this type of entry mode, the hotel chains commit themselves with fewer resources and consequently less control over their foreign business operations.

It can be argued that the greater the degree of control, the volume of investment and the degree of uncertainty, the more companies choose to make FDI in order to guarantee total control, as shown in Figure 1.

Figure 1. Modes of Entry and degree of control

Contrary to this situation, i.e. the lower the degree of uncertainty, the lower the volume of investment and the lower the degree of control, the more the companies resort to franchising.

Direct investment (notably mergers and acquisitions) has been extensively used by companies wishing to expand abroad, changing the characteristics of the industry in recent years (Hill, 2011).

Companies that opt for these modes of entry have the following qualities (Hill, 2011):

- Strong capabilities to deploy their competitive advantages;
- High adaptability to local markets;
- High degree of knowledge of the targeted market;
- High degree of control of product costs and service quality;
- High degree of control of marketing activities;
- High market/sales potential.

There are several reasons why firms choose particular countries to internationalize, which may vary according to regional, geographic, fiscal and political actors (Hitt, Ireland, & Hoskisson, 2011). Within this context, there may also be a number of reasons that help explain why acquisitions is an important entry mode in the hotel industry: access to a more efficient global market, exploitation of technological advances, protection and consolidation of market position, diversification of assets, financial assets that

facilitate investment, a way to eliminate customs barriers, obtaining tax profits, diversification of profit and reduction of risks (Rodríguez, 2002; Valdés, 2003).

The management and franchising contracts have been among the most widely used modes of entry by the large hotel companies because they involve low costs (Garcia, 2013). The American hotel chains are the main protagonists and leaders of the world rankings. These strategies allow companies to be present in several countries. Although hotel chains have targeted mainly developed countries, with the globalization of markets there has been an increase in the number of hotel chains investing in emerging economies.

RESULTS

In the hotel industry, modes of entry are analyzed considering the level of management control and the identification of factors that may influence the choice of these entry modes. The main factors influencing the corporate development of decision making of international hotels and their strategic expansion involve the degree of ownership and the idiosyncratic knowledge embedded in the hotel service (Chen & Dimou, 2005).

The brand image plays an important role in determining the internationalization strategies. In addition, embracing the franchising option of hotel companies that are internationalized is inversely related to size. In turn, the franchising experience and its percentage of franchises granted are positively related to the franchisees' decision to internationalize (Alon, Ni, & Wang, 2012).

The decision to opt for franchising or management contracts differs among companies. For example, from the perspective of cost minimization, luxury hotels may opt for management contracts or acquisitions as an expansion strategy. However, lower-tier hotels may opt for franchising (Chen & Dimou, 2005).

The internationalization process varies from country to country, especially in terms of critical success factors, depending on both the origin and destination country, as a result of market behavior and management decision making processes.

In the case of the Portuguese hotel industry, the critical success factors underlying this internationalization process are the growth capacity of emerging markets and natural resources. In the Portuguese-speaking African countries, Portuguese hotels have looked for low competition of large players of the world hotel industry, allowing very high investments by Portuguese companies, which have also benefited from the proximity of the linguistic and cultural base (Garcia, 2013). Those investments are focused on emerging markets as well as bottom of the pyramid markets, in which products and/or services are customized for each region/country. Among the various entry modes, the most adopted ones have been management and franchising contracts because they involve low costs.

Generally, the internationalization of US multinational hotel companies increases their value (Lee, 2008). Expansion to Asian countries is normally more beneficial than to European countries as it brings more business opportunities.

The internationalization of the Spanish hotel industry does not behave in the same way as that of the world hotel industry. In the Spanish case, companies tend to prefer more flexible modes of operation, acquiring more knowledge and reducing internal uncertainty (Berbel-Pineda et al., 2017). When Spanish hotel companies are located in high-risk environments considered, they prefer to share control with local agents. When they invest in high-income countries, they place greater importance to entry modes such as franchising or management contracts. International hotel companies that settle in urban areas tend to adopt indirect modes of entry in environments with higher risk indices but with higher levels of

development measured by Gross domestic product (GDP) per capita. It is more frequent to find direct investments in highly competitive markets, with a strong local industry, characterized by higher GDP per capita and high rates of FDI (Berbel-Pineda et al., 2017).

The cultural distance, the attractiveness of the market, the international experience of the company, the intangibility of the assets, the size of the enterprises and the number of Chinese tourists who visit each country are determining factors in the choice of the mode of entry of the Chinese hotel chains. The modes involving capital investments prevail over contractual arrangements among Chinese hotel chains (Andreu, Claver, & Quer, 2017).

Besides analyzing the critical success factors that determine the choice of a mode of entry from the perspective of the country of origin, it is also important to analyze the difference between small and large hotel companies. Small hotels with limited multinational experience tend to prefer to enter high potential perceived markets through joint ventures. Moreover, companies that are more capable of developing products are worried about the possible loss of their advantage in countries that are perceived to have greater contractual risks. Although entering high potential perceived markets is more interesting, the existence of investment risks leads small hotels to flee from those investments (Agarwal & Ramaswami, 1992).

The analysis of the modes of entry can also take the perspective of the specific factors of the hotel chains. This can be seen in the case of Chinese hotel chains that prefer input modes involving capital investment, to the detriment of contractual modes. Chinese hotel chains prefer destinations near China, where the entry mode chosen is FDI. Risk aversion as well as cultural distance may have influenced Chinese hotel chains in their decisions to enter foreign markets. In the future, Chinese hotel chains may choose contractual agreements (management or franchising contracts) to avoid higher costs when entering countries with higher cultural distances. However, the chains that serve the middle and lower segments of the market opt for franchising for in order to increase their global reach. In what pertains the company's specific factors, the size of the company, the international experience and the level of intangibility of the assets are important in the decision making process regarding the mode of entry abroad (Andreu et al., 2017).

In the case of Spanish hotel chains, it is clear that the greater the cultural distance, the more Spanish hotel companies tend to opt for FDI and avoid contract agreements. Entering a culturally similar market not only helps avoid the uncertainty of evaluating unfamiliar environments, but also facilitates the establishment and control of integrated operations. In addition, the mode of entry into external markets should be understood as a gradual process that results from the interaction, cultivation and maintenance of relationships over time (Rodríguez, 2002).

DISCUSSION

In a global context, internationalization increases the firms' value, although this depends on where firms decide to internationalize and the opportunities / risks they embrace. Companies with greater ownership advantages can gain pioneering benefits by being the first to enter these countries (Lee, 2008; Agarwal & Ramaswami, 1992).

Companies that have greater capabilities to develop new products/services are normally concerned about the possible loss of their advantage in countries that are perceived to have greater contractual risks. That is, although they are interested in entering in international high perceived potential markets, the existence of investment risks leads them to avoid those investments. It was also possible to realize that the capacity for differentiation mitigates the effect of contractual risks (Agarwal & Ramaswami, 1992).

There are other variables – such as policy variables – that can have a positive impact on investment and technology transfer.

Investments are focused on emerging markets, which is why the products / services are customized to each region / country. The main key success factors of these investments are the growth capacity of emerging markets and natural resources (Garcia, 2013).

It can also be said that there is a positive relationship between international experience and the mode of entry, with the desire to control the value chain. This ratio is measured by both time involved since the hotel firms began to operate abroad, in terms of the number of years, and the degree of internationalization, which reflects their state of international development. The mode of entry into external markets should be understood as a gradual process that results from the interaction, cultivation and maintenance of relationships over time (Rodríguez, 2002; Berbel-Pineda et al., 2017).

The decision of the hotel companies to internationalize is negatively related to the size of the company (Alon et al., 2012). A very important factor in the strategic expansion decision is the degree of ownership and the idiosyncratic knowledge embedded in the hotel service (Chen & Dimou, 2005).

As opposed to the previously referred, the internationalization of the Spanish hotel industry does not behave in the same way as the internationalization of the world hotel industry. In the Spanish case, companies tend to prefer more flexible modes of operation, acquiring more knowledge and reducing internal uncertainty (Berbel-Pineda et al., 2017). When located in risky environments, they prefer to share control with local agents. However, it should be noted that the greater the cultural distance, the more Spanish hotel companies tend to opt for foreign direct investments and avoid contractual agreements (Rodríguez, 2002). In the case of Chinese hotel chains, entry modes involving capital investments prevail over contractual arrangements, since risk aversion may have influenced their entry decisions, as the level of internalization is low in that market (Andreu et al. al., 2017).

In the case of US hotel chains, the decision to expand is based on how this can bring value to the company or reduce risk if they wish to be prudent (Lee, 2008).

The size of the company, the international experience and the level of intangibility of the assets stand out in the decision making in choosing the mode of entry of the Chinese multinational hotel chains in the luxury market segment. In the future, Chinese hotel chains will be able to choose contractual agreements that help avoid higher costs of entering countries with more distant cultures (Andreu et al., 2017).

The success of the expansion of the Portuguese hotel chains may be due in part to the fact that they choose to invest in countries based on the proximity to the linguistic and cultural base, rather than geographical proximity, mainly through management and franchising contracts, as they involve low costs (Garcia, 2013).

The choice between the different modes of entry differs according to the different variables used, so this analysis requires caution. It is also important to analyze from the point of view of the type of market exploited, where it is possible to conclude that franchising is adopted more in small and medium-sized markets, whereas in large luxury markets management contracts are more popular. When quality is not important to the achievement of competitive advantage, management contracts are not widely used and franchising is more likely to be used when hotel size increases (Cunill & Forteza, 2010).

High-income countries attach relatively greater importance to entry modes such as franchising or management contracts. International hotel companies that are established mainly in urban areas tend to adopt indirect entry modes. This occurs in environments not only with higher risk levels, but also with higher levels of development measured by GDP per capita. Besides, it is more frequent to find FDI in highly competitive markets, with a strong local industry, characterized by a higher per capita GDP and high rates of FDI (Berbel-Pineda et al., 2017).

The analysis carried out refers to the different theories evidenced previously, revealing that it is not possible to be restricted when looking at internationalization, given the number of factors that can be considered. However, the hotel industry is part of the tertiary sector in which services play a major role, which is not particularly well covered by traditional internationalization theories as they are more prone to explain the internationalization of industrial firms.

CONCLUSION

The theories of internationalization most emphasized in the literature analyzed in the hotel industry are the Uppsala model and the Eclectic Paradigm. The former is in the sense that there are cases in which the intention was to enter into foreign markets linearly and gradually, especially with low psychic and geographical distances, usually where hotel chains seek to take advantage of new opportunities by exploiting their core competencies through equity and non-equity investment modes.

As regards the Eclectic Paradigm, its interpretation and adequacy to the hotel industry becomes more accessible than the Uppsala model, since the main modes of entry in international markets are in some way related to the ownership, location and internalization specific advantages. Although this theory is predominant when it comes to international business, it has to be adapted to the current internationalization of the hotel industry, in particular the internalization specific advantages.

It is clear that hotel chains exploit international market opportunities by choosing specific locations according to the conditions of these international markets. It is possible to conclude that the main modes of entry have been the FDI, the joint ventures and the contractual agreements (management contracts and franchising). If the internalization advantages can be easily explained through the FDI, the use of joint ventures and contractual agreements make the majority of hotel chains enter international markets without the provision of their services internalization, which can be explained by nature of asset-based services and people-processing services. It is important to refer to that in most situations the agreements signed – management contracts, franchises or joint ventures – among all parties involves a clear definition of the services provided, which helps circumventing the internalization advantages.

In conclusion, within the four main theories indicated in the literature review, of which only three were analyzed, there may not be a single theory that adequately explains the internationalization of the hotel industry, although the eclectic paradigm can easily be adapted to most situations.

Due to changes in global economies and increased competitiveness, it becomes more important to opt for an opportunity with more associated risk than entering the market in a sequential manner that would eventually take longer and may jeopardize opportunities. Furthermore, small and medium-sized companies in the hotel industry tend to adopt different internationalization strategies *vis-à-vis* large multinationals in this industry.

One can conclude that franchising and management contracts are the most common modes of entry in the global hotel industry, because they allow for economies of scale to be more easily achieved and to increase the scope of the hotel chain itself. The same is true of Spanish and Portuguese hotel chains operating abroad, since they prefer these same more flexible modes of entry, while Chinese chains opt for modes of entry that involve greater capital investment and control (FDI). In addition, it should be noted that Chinese and Spanish hotel chains are in an initial state of internationalization.

The analyzed literature also showed that in the hotel industry franchising is more adopted in small and medium markets, while management contracts are more popular in large markets or among luxury brands.

It was important to analyze different markets in the state of evolution of internationalization, namely, Chinese, Portuguese, Spanish and American markets as this helped to understand modes of entry in mature markets as well as the justification of the modes of entry.

Large hotel chains benefit from economies of scale in two complementary ways: they raise important entry barriers: firstly, through the advantages gained by the input mode that exploits these economies of scale, and secondly, because the government of the destination country applies rates that reduce FDI, which reduces international competition.

It is also noticed that the literature on the internationalization of hotel chains focuses on the understanding of the modes of entry and considering three main perspectives: the company / hotel chain and its internal factors; the country of origin; and the market, or country of destination, for which firms intend to internationalize. For each of these perspectives, there are critical factors that, although they may be independent, end up intertwined with the critical factors of other perspectives, and it is therefore relevant to analyze these processes from several points of view. Moreover, there is also a focus on markets where the main chains are concentrated, denoting a lack of analysis of other markets.

FUTURE RESEARCH DIRECTION

Internationalization is very important for firms, in general, and for firms of the hotel industry in particular. Although contractual agreements are important means of entering international markets, and national brands and chains seem to play a vital role in diversifying to foreign markets, it would be of added value to keep abreast of the new perspectives so far not investigated as:

- The role knowledge management plays in generating and adapting valuable resources within the hotel groups;
- The role horizontal knowledge management plays in the generation of competitive advantages within the hotel groups;
- The role competitive dynamics in the hotel industry;
- How competitive rivalry underpins internationalization in the hotel industry.

KEY TERMS AND DEFINITIONS

Consortium: Consists of the association of several companies: which give rise to the creation of a new entity. Consortium allows companies to share resources, divide risks and dissolve cooperation after project completion.

Franchising: Is another organizational form used by companies to compete in highly decentralized industries. In the hotel industry, franchising was launched in the 1960s as an expansion strategy for the Holiday Inn group and since the 1980s it has become a form of international business, especially in the service industry.

Globalization: IT is a worldwide movement toward economic, financial, trade, and communications integration. It is normally envisaged as a lack of trade barriers between nations, which are removed through free trade agreements throughout the world and between nation states. It implies the opening of local and nationalistic perspectives to a broader outlook of an interconnected and interdependent world with free transfer of capital, goods, and services across national frontiers, in which investment opportunities soar.

Internationalization: It is the process of increasing involvement of enterprises in international markets. It involves a strategy carried out by firms that decide to compete in foreign markets. It involves cross border transactions of goods, services, or resources between two or more firms or organizations that belong to two different countries.

Internationalization Process: It involves the emphasis of a trajectory of a company in its transition from a national market to a particular foreign market. It normally involves several entry modes (exports, FDI, franchising, etc.) that exert a critical influence on the subsequent trajectory, as well as on cost related to the internationalization process. The two most important theories that explain the internationalization process are the Uppsala model and the network-based approach.

Joint Venture: Is another growth vehicle available to hotel/business companies. These types of agreements are considered as legal contracts whose ownership and management of the organization are shared by more than one organization and are normally used when the benefits outweigh the additional costs.

Management Contract: Is a long-term agreement in which the owner of the property contacts an international hotel company in order to manage the hotel. Through management contracts, hotel chains are responsible for all hotel operations, namely by implementing systems and procedures, selecting the hotel manager, and enforcing their human resources and quality policies.

Network-Based Approach: It based on the industrial networks theory, which states that firms evolve on the basis of established relationships. It considers the companies' internationalization process through their integration into networks and relationships. Following this perspective, the internationalization process occurs in interactive environments where companies of a well-established network of companies have an opportunity to develop new relationships that give them access to broader markets in other countries.

Strategic Alliances: Are designated as intermediate modes of entry in international markets. They are normally carried out by companies that have experience and knowledge in certain specific areas, but need to complement forces in other areas. Strategic alliances aim to share and/or exchange products, services, knowledge, and profits.

Uppsala Model: It has been one of the most discussed dynamic theories in Nordic School and International Business Studies. It explains the process of internationalization of companies. It explains how organizations learn and the impact of learning on the companies' international expansion. This theory defends that the companies' internationalization process is carried out in stages, from non-regular exports to the establishment of companies abroad.

Similarities and Differences Between Word-of-Mouth and Electronic Word-of-Mouth

INTRODUCTION

One of the most common behaviours after enjoying a product, especially if it is a tourist service (Woodside & Moore, 1987), is comment the experience. Habitually, this behaviour is called Word-Of-Mouth (WOM). With the appearance of Internet, this behaviour began to occur through the new media (Gruen, Osmonbekov & Czaplewski, 2006, Hennig-Thurau, Gwinner, Walsh & Gremler, 2004) and is called electronic Word-Of-Mouth (eWOM). Both concepts have been considered the same but it is necessary to perform analyses and comparisons to verify this fact. To compare both concepts, the causative variables of recommendations generation will be analysed in one of the most important economic activities, the tourism sector. Tourism literature recognizes the importance of emotions, satisfaction and post-purchase behaviour (Bigné, Andreu, & Gnoth, 2005), and diverse studies show emotions as antecedent of satisfaction and behavioural intentions (e.g., Grappi & Montanari, 2011; Han & Jeong, 2013; Yuksel & Yuksel, 2007). Some studies have found a positive relationship between satisfaction and the intention to recommend (Lii & Lee, 2012; Prayag, Hosany, Muskat, & Del Chiappa, 2017), but other authors raise doubts about the existence of this relationship (Dolnicar, Coltman, & Sharma, 2015; Yang, 2017).

At present, consumers are looking for a lot of information on Internet before making any decision. Among the multiple information available, the comments and opinions of other consumers are the most valued. Consumer-to-consumer (C2C) communication in social media has become a critical element for companies, especially for service companies. The importance of C2C communication has made fundamental to analyse the causes of eWOM generation and the effects that eWOM has on the potential consumers (Serra & Salvi, 2014). eWOM has overshadowed the traditional WOM and created a new line of research. As noted in previous studies (e.g., Filieri & McLeay, 2013; Litvin, Goldsmith, & Pan, 2008) there is a need for more research that explores eWOM and tourist behaviour.

Although some authors have identified emotions as precursors of positive word-of-mouth, but eWOM in comparison to traditional WOM (recommendations to relatives and friends) requires a plus to be generated. WOM are made through an 'unplanned' process when there is a chance to do it in casual meetings or somebody ask. However, eWOM requires a conscious, planned action with slightly more effort involved in uploading comments to Internet. The purpose of this chapter is to examine the

DOI: 10.4018/978-1-7998-3473-1.ch111

differences and similarities between traditional WOM and electronic WOM, based on empirical data, to see if they are the same thing in different supports or different things. To achieve this objective, it will be examined the role of six variables (Service Quality, Perceived Value, Customer Satisfaction, Brand Reputation, Customer Loyalty and Emotional Experience) in WOM and eWOM generation, in the context of lodging services. Moreover, it will be analysed the relationship between the two types of recommendations. A statistical analysis is performed based on the use of Structural Equation Models (SEM), specifically by Partial Least Squares (PLS) technique. The main conclusion is that the two types of recommendation are not exactly the same. In both cases, Emotional Experience is very important but Customer Satisfaction is a differential element.

BACKGROUND

First, must briefly comment on a set of concepts that intervene in the behaviour of the customer and that may have an effect on the client's intention to comment on their experience. Due to the nature of the services (intangibility, simultaneity and heterogeneity), the quality assessment carried out by clients has a global focus, taking into account what happens before, during and after provision of the service. This implies that everything from the request for information, prior to the purchase decision, to the buyer-seller relations, very subsequent to the provision of the service, is important for the client. Clients perceive the Service Quality as a set of attributes that are taken into account to perform the overall evaluation of the service (Choi & Chu, 2001).

The concept of value can be applied to various fields of knowledge (Nasution & Mavondo, 2008). Normally, definitions of value include aspects related to price, quality and customer perception (Slater & Narver, 2000). In addition, customers' expectations regarding the product should be considered (Fornell, Johnson, Anderson, Cha, & Bryant, 1996). Value is a process of interpretation of the consumer in relation to the product (good or service) consumed, measuring the benefits and sacrifices including both monetary and non-monetary (Nasution & Mavondo, 2008). Mittal & Sheth (2001) emphasize that providing positive value (more benefits than sacrifices) to customers is an important factor for the success of companies. Nasution & Mavondo (2008) indicate that the value provided to the client is associated with the generation of positive WOM.

Customer Satisfaction is a comparison between the service expectation and the perceived service (Parasuraman, 1997; Raval & Grönroos, 1996). There is a logical and important positive relationship between Service Quality and Customer Satisfaction and it is widely contrasted in the literature (Da Silva & Alwi, 2008). In fact, the Service Quality is usually considered as the satisfaction of the client, that is to say, meet the requirements that the consumer expects to find before the provision of the service.

Keller (1993) defines brand image as the perception in consumer memory and adds that brands are an intangible asset of companies that are difficult to imitate. It is considered that brands are a sum of elements that represent an organization (Da Silva & Alwi, 2008), and is the company vision from customer perspective (Grönroos, 1990). In this sense, it is considered that the brand image or reputation is generated through an accumulation of consumer reactions to the experiences lived (Davies & Chun, 2002). In this chapter, reputation (Loureiro & Kastenholz, 2011) and image (Da Silva & Alwi, 2008) will be considered as synonyms. A strong and positive corporate Brand Reputation not only helps a company achieve a competitive advantage, it also stimulates repeat purchases (Da Silva & Alwi, 2008).

Customer Loyalty has been defined in many different ways. Although the customer's intention to repeat purchase selection is central to all definitions, as Kabiraj and Shanmugan (2011) points out, loyalty

is a very complex multidimensional concept, influenced by a large set of variables. Attitudinal approach depicts loyalty as a psychological state that the customer may attain as a result of the relationship with the firm. Customer may voluntarily maintain that relationship based on the benefits that receives during the relationship (Caruana, 2002). This approach advocates the idea that the foundation of true loyalty is a positive attitude toward the firm and this positive attitude is necessary for a repeat purchasing behaviour. The importance of customer's loyalty to long-term company's sustainability is widely acknowledged (Callarisa, Sánchez, Cardiff, & Roshchina, 2012).

In recent years, there has been more talk about the tourist experience than about service quality. Tourist experiences include satisfying and pleasurable emotions (Coghlan, Buckley & Weaver, 2012) and positive emotions are associated with memorable experiences (Tung & Ritchie, 2011). As Xiang, Schwartzb, Gerdes Jr and Uysal, (2015) state, the guest experience is an extremely complex construct. Depending on the research design and methods, researchers could get very different pictures of what constitutes experience. Customer experience can be defined as the entirety of the interactions a customer has with a company and its products. Positive emotional experiences in the hotel context could be defined as: service encounters that exceed customer's expectations and flawlessly executed; design and delivering of customized, innovative and unique products; surprising and unexpected levels of service; a touch of additional differentiation.

The six variables exposed are potential causes of recommendations generation, regardless of the communication channel chosen. Therefore, it is possible to propose a causal model with a dependent variable (generation of recommendations) that is affected by the independent variables indicated.

WOM and eWOM

The WOM analysis goes back to the eighties, with studies like that of Woodside and Moore (1987). The eWOM analysis is much later and appeared with studies such as Hennig-Thurau et al. (2004) and Gruen et al. (2006). The eWOM, also often referred to as online reviews, online recommendations or online opinions, has gained importance with the emergence of new technology tools, especially with the emergence of Internet 2.0 and social media. Litvin et al. (2008) define eWOM as all informal communications directed at consumers through Internet-based technology related to the usage or characteristics of particular goods and services, or their sellers. Traditional WOM has evolved into eWOM in the new digital era and the main differences can be identified in the reach of the reviews' impact (number of people who can be influenced) and the speed of interaction: "compared to traditional WOM, online WOM is more influential due to its speed, convenience, one-to-many reach, and its absence of face-to-face human pressure" (Sun, Youn, Wu, & Kuntaraporn, 2006).

Companies are increasingly seeking to understand the factors that influence eWOM generation, as well as the impacts resulting. The tourism industry is strongly affected by eWOM and hotels are probably the most affected (Serra & Salvi, 2014). Many of the studies carried out have analysed the WOM, that is, the comments made person to person in a traditional way, but the analysis of eWOM is very recent. In many cases, it is considered that eWOM is essentially the same as WOM but by electronic means. The situations in which it occurs suggest that this equivalence should not be assumed without having a statistical comparison. The WOM is usually the result of search for a topic of conversation in family or friends' meetings or the answer to a question or a doubt from someone. The eWOM implies a dissemination of information without a specific addressee and with the sole purpose of making known something that has surprised positively or negatively.

The main objective of this chapter is to make a comparison between both types of recommendation (WOM and eWOM) by means of a statistical analysis on a sample of hotel customers. This is to provide empirical analysis to indicate if there is any difference between the two concepts, beyond the speed of dissemination of comments. To do this, two causal models will be analysed, one for each type of recommendation, to compare causal effects, and finally the two will be integrated in a single model in which one type of recommendation is the cause of the other type. Although they are different concepts, it is possible that there will be a positive relationship between WOM and eWOM.

COMPARISON BETWEEN WOM AND eWOM

Methodology

To test the hypotheses, a questionnaire has been designed containing some items already used in previous studies (e.g. Han & Jeong, 2013; Loureiro & Kastenholz, 2011; Sun et al., 2006) and others from own elaboration. To measure items, a five-point Likert scale has been used, and questionnaire was completed with questions dealing with demographic aspects and trip information. The fieldwork was done in the second part of 2017. A total sample of 240 valid questionnaires was obtained in the personal survey conducted in the Maldonado-Punta del Este conurbation (Uruguay) between people who had lodged in a hotel during the previous six months. In all cases, they were asked about their last stay in a hotel. The socio-demographic profile of the resulting sample is fairly balanced, and questions related to the trip show type of trip and accommodation chosen (Table 1).

The research model has been tested using Partial Least Squares (PLS) technique, a variance-based Structural Equation Modelling (SEM). More precisely, this study uses SmartPLS 2.0 software (Ringle, Wende, & Will, 2005). While the results differ little for the alternative weighting schemes, path weighting is the recommended approach (Henseler, Ringle & Sinkovics, 2009).

Results

Before proceeding to analyse proposed models, it is necessary to analyse the measurement model. Individual item reliability is considered adequate when an item has a factor loading (Table 2) that is greater than 0.707 on its respective construct (Carmines & Zeller, 1979). Construct reliability is usually assessed using Cronbach's Alpha (Cronbach, 1970) and composite reliability (Anderson & Gerbing, 1988; Bagozzi & Yi, 1988). When both values are greater than 0.7 it is considered as a valid reliability criterion (Nunnally, 1987), as in this case (Table 2).

To assess convergent validity was examined the Average Variance Extracted (Fornell & Larcker, 1981). AVE values should be greater than 0.50 (Bagozzi & Yi, 1998; Fornell & Larcker, 1981), and are greater than 0.63 (Table 2). Discriminant validity indicates the extent to which a given construct differs from other constructs (Anderson & Gerbing, 1988). There are two approaches to assess discriminant validity (Chin, 1998) and these conditions are satisfied for all latent variables.

After testing the measurement model, it proceeded to analyse proposed causal relationships. PLS-SEM relies on a nonparametric bootstrap procedure (Davison & Hinkley, 1997) to test the significance of estimated path coefficients and with this information t-values are calculated (Hair, Hult, Ringle, & Sarstedt, 2014). At this stage, values for path coefficients and Student's t are obtained (Table 3).

Table 1. Characteristics of the trip (own elaboration)

	Frequency	Percentage
Reason for the trip:		
Leisure.	171	71.25%
Job.	30	12.50%
Visit relatives.	29	12.08%

Table 3. Structural Model (own elaboration)

	WOM generation ($R^2 = 0.511$)				eWOM generation ($R^2 = 0.302$)			
	Path Coefficients	Standard Error	T Statistics	P value	Path Coefficients	Standard Error	T Statistics	P value
Service Quality:	0.026 ^{ns}	0.149	0.177	0.430	-0.151 ^{ns}	0.177	0.852	0.197
Perceived Value:	-0.073 ^{ns}	0.125	0.584	0.280	0.094 ^{ns}	0.131	0.718	0.236
Customer Satisfaction:	-0.010 ^{ns}	0.173	0.058	0.477	-0.490**	0.173	2.831	0.002
Brand Reputation:	0.154 ^{ns}	0.142	1.084	0.139	0.212*	0.155	1.373	0.085
Customer Loyalty:	0.149 ^{ns}	0.139	1.067	0.143	0.211*	0.162	1.305	0.096
Emotional Experience:	0.511***	0.123	4.162	0.000	0.507***	0.140	3.619	0.000

* $p < 0.1$; ** $p < 0.01$; *** $p < 0.001$; ^{ns} not significant.

In the first causal model, only Emotional Experience has a significant effect on WOM generation (Table 3), but it allows explaining a very important part of the variance ($R^2 = 0.511$). In the second causal model, Emotional Experience has a significant positive effect and Customer Satisfaction has a significant negative effect on eWOM generation (Table 3). In addition, Customer Loyalty and Brand Reputation have slightly significant positive effects (at 0.1 level). With all, second model explains less variance than first ($R^2 = 0.302$). This indicates that there are differences in the causes, especially in the importance of Customer Satisfaction.

When focusing on WOM and eWOM, there is a correlation between the two variables of 0.390 and if a simple regression is considered, in which one of the two types is the cause of the other, the effect is important ($\beta = 0.418$) and significant (p value = 0.000), regardless of which is dependent or independent. But if the two causal models analysed in Table 3 are linked by a causal relationship between the two types of recommendation, this causal relationship has a low level of significance (p value = 0.07). This suggests that WOM and eWOM have similarities but cannot be considered to be the same concept in different support (the correlation is too low) or one is causing the other (there is little significance in the causal relationship when other variables are introduced). The differences between both types of actions

Table 4. WOM and eWOM generation (own elaboration)

	Sample Average	Standard Deviation
WOM generation:		
WOM01	3.664	1.114
WOM02	3.299	1.155
WOM03	3.175	1.126
eWOM generation:		
eWOM01	2.325	1.099
eWOM02	2.227	1.168
eWOM03	2.186	1.176
eWOM04	2.466	1.276
eWOM05	2.288	1.254

can be seen even in the purely descriptive data, and the same sample has clearly different intentions in terms of WOM generation and eWOM generation (Table 4).

SOLUTIONS AND RECOMMENDATIONS

The provision of emotional experiences to hotel guests may constitute a powerful review-generating factor in hospitality services, and the data in this study corroborate this assumption. Several professionals consider that the relationship between tourist experience and eWOM generation is so strong that, in reality, commenting on the experience would be part of the experience. This level of integration is only an assumption of some people, but the causal relationship is more than plausible (Jang & Namkung, 2009). The discussion regarding emotional experiences and eWOM generation is complex to clarify because statistical tools hardly allow the high level of precision that would require:

- The simplest interpretation is to consider that the online content that a person generates is the result of an emotionally shocking experience. The person seeks to communicate their experience to make known something positive or negative that has happened. Generally, greater the surprise, greater the intention of commenting. Essentially an action subsequent to the enjoyment of service and that allows an emotional satisfaction based on the remembrance of the experience.
- It can be considered the possibility that uploading content online is not an action subsequent to the experience but the final phase of the experience. The vision of eWOM generation as part of the experience would be reaffirmed by the trend, now possible thanks to mobile technology, to generate eWOM during the experience. It is common for some people to perform a “live broadcast”, or almost, of what they live during an event or a trip.

Regardless of which explanation is considered correct to understand the relationship between emotional experiences and generation of recommendations, what this study indicates is that experience is fundamental for both types of recommendation (traditional and electronic). This implies that entrepreneurs from all sectors, but especially those that offer services linked to leisure, should contribute something more to the client, an affective and emotional component that goes beyond expectations. This will generate recommendations and positive comments, both person to person and on Internet, which will be the best possible promotion, as the opinions of other clients are the most valued information source. The rest of factors need more analysis to know their importance, but positively surprise the customer is a fundamental element for success.

FUTURE RESEARCH DIRECTIONS

The relationship between customer satisfaction and the positive eWOM has been analysed but there are still no conclusive results (Lii & Lee, 2012; Prayag et al., 2017). Swanson and Hsu (2009) reach the conclusion that customers who experienced satisfactory incidents are not necessarily more likely to recommend the service provider or to convince others to use the service provider than their dissatisfied counterparts. In the context of restaurant-services, Yang (2017) did not find support for the link between satisfaction and positive eWOM intentions. Dolnicar et al. (2015), in their meta-analysis of methodologi-

cal aspects of guest surveys in the context of tourism destinations, also raise some concerns regarding the link between satisfaction and intention to recommend.

In the present work, Customer Satisfaction does not have any causal effect on WOM generation, but has it on eWOM generation. It is striking that the sense of the causal relationship between Customer Satisfaction and eWOM generation is negative, that is, the more dissatisfied customer the higher is the probability of commenting in the online environment. This would indicate that the eWOM, for the sample studied, is a form of protest for a bad service that seeks a great impact among the potential customers. Therefore, the relationship between Customer Satisfaction and eWOM generation deserves additional research effort and, particularly, in the hospitality context. In addition, the rest of variables cannot be discarded in future studies, especially Brand Reputation and Customer Loyalty. These two variables have a moderately significant effect on eWOM generation. In future studies should be deepened in the comparison between both types of recommendations and the causal variables, both through qualitative and quantitative studies.

CONCLUSION

The eWOM is not identical to the WOM and this fact must be taken into account by both researchers and managers. They have similarities, such as the importance of emotions and the client's experience in their generation, but also differences. Based on the results of this study, it is possible to affirm that eWOM is more complex, since more significant variables have been found but with less explanatory power. This implies that they must be considered as distinct concepts with different causes and consequences, which should be analysed in future studies that complement the current work and overcome its limitations (study with a small sample in a specific region and sector). In a more generic way it could be affirmed that human behaviour is not equal offline and online and cannot be considered equivalent.

KEY TERMS AND DEFINITIONS

Brand Reputation: Opinion of the clients about a company or product.

Customer Loyalty: Affective and behavioral fidelity to a product, brand, or company.

Customer Satisfaction: Comparison between the client expectations and the valuation subsequent to the enjoyment of the product.

Electronic Word-of-Mouth (eWOM): All informal communications directed at consumers through Internet-based technology related to the usage or characteristics of particular goods and services, or their sellers.

Emotional Experience: Affective effect generated by the enjoyment of the product.

Perceived Value: Comparison between the costs and benefits of a product.

Service Quality: Consumer perception of the technical and objective characteristics of a service received.

Structural Equation Model (SEM): A statistical method studying causal relationships amongst data. It uses a confirmatory approach of multivalent analysis that applies a structural theory related to a given phenomenon.

Word-of-Mouth (WOM): All informal communications person to person related to the usage or characteristics of particular goods and services, or their sellers.

Mobile Culture for Tourism Communication

Pedro Andrade

Institute of Social Sciences, Communication, and Society Research Centre, University of Minho, Portugal

INTRODUCTION: WHY MOBILE CULTURE FOR TOURISM COMMUNICATION?

Mobile culture is emerging as a new paradigm of social action and discourse. It works as a sort of template for practicing, learning and applying information and knowledge, within multiple economic, political and cultural activities within the urban fabric. This phenomenon involves capitals, persons and objects, which are profoundly on the move across global and local arenas. According to John Urry (2007) and Mimi Sheller (2006), *social mobilities* even constitute the leading process shaping contemporary societies and urban cultures. Likewise, interpretation methods of all social realms are being shaken by quick and deep discursive movements, for instance in what concerns the analysis of cultural heritage (Cessari, 2011; Andrade, 2013) or mobilities (Giannotti, 2008).

However, such mobilities of cultural goods, services and interpretation are not desirable or even possible, without adequate *communication* among the main stakeholders involved in this novel reality. In other words, contemporary societies face a critical *intercultural* process (Piller, 2011; Paulston, 2012), that is, the encounter or clash between national citizens and foreigners, be them tourists (Andrade, 2014) or immigrants (Benson, 2012; King, (2013). And the correspondent communication of local, national or international information and knowledge are being activated, more and more, through *digital mobilities* and the underlying discourses. Among the central instruments which facilitate this communication, *mobile devices* such as cell phones are becoming prominent (Ling, 2009). For instance, according to André Caron (2007), when exchanging text messages, young people don't just share information, but develop verbal performances that create knowledge and culture. And, beyond culture, mobile devices are becoming a cult (Goggin, 2006), a posture that, occasionally, may bring pleasure but also some risks, within the present *risk society* (Beck, 1992, 2008).

In sum, mobile devices are transforming the way we understand and sense urban and intercultural processes. Recently, mobile devices users are dealing with sophisticated new information and knowledge technologies, via *Virtual and Augmented Reality* apps, which may help them to get more and deeper experiences and understanding of their everyday life in urban places, contexts and territories. Following this trend, city planners are developing intelligent strategies for experiencing and interpreting practices, knowledge, culture and arts related with urban mobilities. Such initiatives aim to redefine not just local life and national citizenship, but also, at an international level, intercultural exchanges between the citizen and the Other, that is, visiting foreigners such as tourists or immigrants (Arvastson, 2006).

Within this perspective, the purpose of the following text is twofold: firstly, to define the main ideas and concepts which clarify the process of mobile culture, activated through the use of mobile devices (cell phones, etc.). Secondly, inquiry why and how mobile culture and its devices facilitate or difficult one of the most relevant processes in the contemporary city, that is, *urban mobilities* and its *modes and means of communication*. This text considers just one of such mobilities, the tourism travel, and focus on

DOI: 10.4018/978-1-7998-3473-1.ch112

the most relevant social and cultural exchanges of competences and performances among, on one side, native citizens of a destination place and, on the other side, tourists visiting this locality (Andrade, 2017).

BACKGROUND: STATE OF THE ART ON MOBILITY CULTURES AND TOURISM

Mediatization can be briefly defined as a social process which translates, shapes and frames all other processes and discourses within contemporary society. It was studied, among other authors, by André Jansson (2017), in connection with the ideas of individualization and globalization, and mainly in what regards mobile middle-class lives and *post-tourism*. In particular, it is important to know how media-tization is culturally legitimized, in a moment when connectivity and mobility are central elements of self-realization.

Within such media hegemony, *digital media* acquired an even more protagonism. Some practical applications of these ubiquitous digital media include tourism, banking and health. In fact, digital devices are profoundly transforming human experience and knowledge. This is visible at a global geographic dimension, within processes of deconstructing and reconstructing urban environments, local life worlds, infrastructures, networked practices and even global geopolitics. Identities are also changing along subjective, perceptive, and affective levels, in terms of digital users' engagement with the spatial world (Felgenhauer, 2017).

This *digital daily world* is a context based on *mobilities*, which are circumscribed as social processes of displacement among diverse areas of cities, regions, countries or other social spaces, at a local and global levels. Mobilities are simultaneously shaped and feeding economy, politics, culture and all other realms of society. Within this context, everyday life is an arena where examples and applications of such phenomena can be easily found. Sara Paiva (2018) inquires how recent technological innovative platforms may develop daily mobility of visually impaired people. The ultimate aim for these social actors as users of such appliances, is their societal inclusion. In this sense, some practical applications are obstacle detection systems, indoor and outdoor navigation and transportation sustainability systems. At a macroeconomic and policies level, such improvements may be undertaken by companies as well as by municipalities, in order to enhance *global and urban mobility* (Kolke, 2014).

Likewise, tourism is an activity where mobilities are to be found in the most unexpected ways, within the intersections of globalized mobility and everyday *mobile tourist* practices. Kaya Barry (2017) points out the apparently irrelevant action of packing a bag for a travel. The author shows how idealized tourists destinations influence their daily actions, and specially their everyday experiences of movement such as this minimal action of preparing a bag for a voyage. To prove such thesis, Barry uses multiples photographic documentation and interviews collected with tourists in hosteling accommodations.

Many of these mobility phenomena are more systematized within one of the seminal books written by John Urry and Jonas Larsen, with the title *Mobilities, Networks, Geographies*, and published in 2016. The authors defend that, as for social mobilities, physical meetings aren't less fundamental to human life than virtual travels. In effect, both are interconnected and equally necessary. Moreover, the book establishes an interesting typology of modes of mobility, in our world where there is a substantial increase in long-distance travels and in communicating through mobile phones, text messaging, emailing and videoconferencing. These geographies of social networks include the following five *interdependent mobilities*: physical travel of people; physical movement of objects; imaginative travel through mass media; virtual travel inside cyberspace; and communicative travel via other more primitive means e.g.

letters, telegrams and telephone. These interconnections between different mobilities require efficient systems of coordination among them.

Another synthetic essay, conducted by Adriana de Souza Silva and Mimi Sheller (2014), criticize the way previous studies cope with mobility, by focusing on virtual mobility and personalized communication. On the contrary, it is necessary to concentrate on mobile media in context, such as people using transportation networks, navigating urban spaces, and sharing content and messages within social networks or inside mobility events such as tourism travels. In sum, it is crucial to emphasize the relations among location, mobile technologies and mobility, in order to redefine *mobile communication* and *mobile sociality*, operated through *locative media*. In this way, concrete applications of mobility in the social fabric (such as mobile art, mobile gaming, architecture, design and urban planning) may better connect citizens and tourists to their urban contexts.

In fact, mobilities are defining a new lifestyle, predominant and maybe dominant in the present world. Scott Cohen and collaborators (2014a) argue that, among other phenomena on the move, *mobile lifestyles* include the reshaping of information, knowledge and cultural values. This process unfolds through everyday repetitions and routines, such as daily bodily performances, that produce new meanings to our lives. Even social sciences are being transformed, via *mobile methods* and through a reconceptualization that articulates the ideas of mobility, immobility, belonging and mobile identities (Urry, 2000).

It is crucial to note that our mobile world includes *gendered mobilities*. Tim Cresswell (2016) interconnects gender with mobility and social justice, underlying that women can reach more agency and freedom through mobile activities inside health, education and political participation. Ultimately, women's wellbeing is associated with mobile actions conducted both socially and geographically.

Several practical applications of mobilities are developed by urban designers. The METPEX research project, conducted by Coventry University, aims to resolve transport and traffic problems that European cities are experiencing, which cause environment damages. For such purpose, the project members developed a *mobilities design* approach, where they consider needs of transport users in balance with urban sustainability targets. This aim was pursued through a specific instrument developed for measuring passenger experience, which reports and analyses the passenger journey. The practical results indicate how to attract travelers to use more public transportation, in order to reduce traffic congestion (Tovey, 2016).

Such concern for the organization of urban mobilities is so urgent that several *practical guides* are being published along last years. One of the most complete was written by Sachin Date (2015). It covers a plethora of application fields pertaining to *wireless communication*: digital cellular networks definitions of "digital" and "cellular", mobile apps ecosystems, how to evaluate consumer mobile apps, etc. For decision makers, and especially in the case of corporate professionals, the author explains how to develop *mobile marketing*, in order to increase sales, obtain customer satisfaction and operational efficiency, and how to reach a true enterprise *mobility*. In particular, in the areas of Hospitality, Travel and Tourism, multiple advices are suggested on brand projection and about mobile enabled websites, augmented reality or GPS based selling techniques. More advanced strategies include *mobile enabled ecosystems*, e.g. 'wearables' for automotive mobility and activities inside the Internet of Things (Fortino, 2014).

For its part, the *Routledge Handbook of Mobilities* (Adey, 2014) has a more *encyclopedic* purpose. In particular, the authors highlight the relevance of mobilities as a central concept and keyword within the *social sciences*. Multiple approaches and debates, as well as methodologies and techniques innovation, case studies and reconceptualizations, are described and evaluated. A *typology of mobilities* include infrastructure, services and events mobilities. This research can be applied to multiple fields and activities, e.g. transport, migration, tourist and feminist studies.

In some way, the book by Vogl's team (2013) takes a step further: mobilities are rehearsed here within the *mobile discourse* that presided at the very realization of this collective work that, in occurrence, analyzes mobilities. In fact, the book allows the sharing and *mobility of meanings*, among the analyses produced by researchers from different origins, such as social sciences, artists and art theorists. Concretely, such cross-disciplinary mobility, while adopting a mixed media and visual representations approach, uses texts and images to debate regulation and structure of mobility, mobility policies of global corporations, bicycle policies on public space and migration flows, among other issues.

Therefore, it seems that, within contemporary societies, social and cultural mobilities, and in particular *mass tourism* (Bramwell, 2004; Blackman, 2005; Buhalis, 2011; Conrady, 2012), happens to be some the most important activities that mobilizes mobilities. Pau Pons (2012) shows that Mediterranean region, the largest tourist destination in the world, owes its economic success to parallel cultural and aesthetic phenomena. There, tourists' experiences are articulated with (and remade by) mobilities and performances conducted by local actors and cultures inherent to destination places.

Such mobilities' social processes induce important consequences and teachings. In what concern *Tourism Studies*, another essay (Molz, 2012) intends to shake research routines on mobilities within this field. The author argues that classical concepts on tourism no more translate the present situation, such as landscape, the tourist gaze, hospitality, authenticity and escape. These notions can profitably be replaced by the following terms: smart tourism, the mediated gaze, mobile conviviality, re-enchantment and embrace. In particular, togetherness may be reached through interactive travel. This last idea can be defined as a voyage where the traveler aims to be in touch simultaneously with friends, family members and strangers, via new practices such as location-aware navigating, travel blogging, etc.

Likewise, travel writers are rebuilding their practice (i.e. the writing that involves voyage, migration, mobility and displacement), by creatively using experimental techniques. The confessed target is to overcome colonial or Eurocentric tradition in *travel writing* (Edwards, 2012).

Ultimately, the concept of tourism itself and the connected leisure patterns were put into question by Peter Burns (2008). New articulations must be made among mobility, media and citizenship, in order to take in account the new realities of post-modern youth, independent mobility and hypermobility within global space.

Last but not the least, for applications of mobile cultures in the economic world, in order to develop and practice a sustainable *mobile business*, see: Bhuvan, 2008.

FOCUSING ON MOBILE TOURIST COMMUNICATIONS

Departing from previous considerations on cultural mobilities, it is important now to focus on one of its more profoundly related ideas, i.e. *tourism communication*. In fact, mobile culture, although revealing to be an end in itself, often works as a means to achieve a deeper communication between citizens and tourists across a destination place.

One *tourism communication* issue, somehow unsuspected, is climate change. Indeed, at the macro-social level, tourist industry and global mass tourism, and at the microsocial level, daily tourist behaviors while communicating with locals, influence the climate of the places of destination, in the long term (for instance, via the increase of traffic pollution). It is therefore necessary to change tourism policies in conjunction with sustainable climate policies (Cohen, 2014b).

This and other real problems lead to questions pertaining to the *morality of tourism* (Mostafanezhad, 2014). Any tourism encounter presupposes a moral encounter. And during touristic voyages, exchange experiences hide power relations, that often dictate moral reconfigurations within visited societies.

Language is other powerful instruments of human communication, especially in what regards tourism communication. An emerging field, Sociolinguistics of tourism, debates how language constitutes identity, power and social difference in the context of tourism mobilities. Some sources are used by Jaworski (2007) to demonstrate this argument: on one hand, classical sources such as interviews with tourists, service encounters, analysis of postcard messages and guided tours; on the other hand, sources involving recent methodology, e.g. TV holiday programs or digital interactional data.

More specifically, *tourism discourse* has been analyzed and interpreted for several years, as one central part of tourism communication's teaching and research. Corpus including spoken, written and visual texts, were used to clarify the ideas and practices of space and representation within the tourist experiences or performance, as well as to reflect on the pursue of tourist identity via the authenticity of destination places (Jaworski, 2005).

The following example corroborates this power of tourism discourse: reflexions on several case studies demonstrated that *tourism marketing* often promotes insignificant places as desirable tourist destinations. Such propaganda uses language from diverse cultures in relation with the concept 'tourism gaze', among other ideas (Held, 2018).

In sum, the whole *tourism industry* has been profoundly transformed with the advent and dissemination of electronic technologies and the correspondent communication phenomena (Reilly, 1990). The effects of digital communicative processes and methodologies cover economic, social, regional, social, marketing and cultural branches of tourism activities (Pease, 2007).

Moreover, for other specific reflections and empiric analysis on tourism communication, e.g. on accessible tourism for disabled people, see Westcott (2004).

SOLUTIONS AND RECOMMENDATIONS

On Technologies and New Media for Tourism

This section intends to clarify some more intense articulations between mobile cultures and tourism communication, the two subjects treated in the precedent pages. In this confluence, the reported issues, controversies and problems require the definition of means and methods that could substitute complexities, biases and abuses perpetrated with such appliances, with more practical and democratic uses.

Debates on tourism technologies

Previous discussions: states and European policies stakeholders, city planners, scientific communities, corporations, among others, have been debating for several years the impact of information and communication technologies in tourism, related with contextual variables, within periodic conferences and other regular events. For example, in what regards sustainable local development, environmental and climate change, cybercities, second homes (Graham, 2004; Hall, 2004, 2005; European Communities, 2005; Gössling, 2006; Girard, 2009; Hannam, 2010; Cunha, 2011; Francesconi, 2014; Hanna, 2015).

Following anterior editions, in 2006 a major event took place in this subject at Bilbao, the *conference ENTER - International Conference on Information and Communication Technologies in Tourism* (Klein,

1996). The scope was to rethink the whole process of touristic goods and services, from a technological point of view. For instance, connect, on one side, telecommunication and information systems in tourism, to, on the other side, the dissemination of information for eventual users. In particular, the redesign of touristic products and the redefinition of standardization norms, could help to restructure tourism values. The target public was composed by researchers, system developers, principals, tour operators, travel agents, customers, among other users.

Another conference in a connected direction tried to report the recent impressive technological metamorphoses related to mobilities, occurred in the last years of the 21th century first decade, and the respective impacts on society (Cunha, 2011).

In 2013, the series of conferences more focused on Information and Communication Technologies in Tourism was retaken (Cantoni, 2013). The subjects discussed testify advances in two interconnected fields: (a) on one hand, digital media in general: for instance, web site and search engine optimization, eLearning, recommender systems, technology adoption and diffusion, online communities, social media and Web 2.0, user generated content; (b) on the other hand, digital media applications on tourism activities: for example, electronic tourism marketing, tourism management and decision support, mobile technologies and applications in tourism, e-intermediaries and networks in tourism, customer research in e-tourism.

Such particular themes were developed in 2014. Other themes were added, e.g. electronic distribution for hospitality and travel products, virtual travel communities, to name just a few (Xiang, 2014).

In 2015, new debates considered big data and analytics, mobile sensors and geosocial services, augmented reality, wearable computing, smart tourism, responsive web design and management, and eTourism for development (Tussyadiah, 2015).

Two years later, more recent controversies were debated, such as semantic technologies, electronic distribution and online travel reviews, eGovernment, sharing economy, digital strategies within digital economy. Research advances and innovative ideas were reported, as well as industrial case studies (Schegg, 2017).

In 2018, besides some recurrent themes, the latest research was publicized (Pesonen, 2018), e.g. about online travel reviews, gamification (Flanagan, 2009; Burke, 2014; Jin, 2016), electronic distribution, online education and learning

Finally, in 2019, the focus was directed to virtual reality, peer-to-peer accommodation, hotel technology, robotics, and recommendation systems (Pesonen, 2019).

Solution / recommendation: these and other conferences, as well as seminars and other scientific events, testify the dynamic debate that is being conducted on these urgent issues. Therefore, such effort must go on and be supported by states, municipalities, intercultural scientific and technological communities, corporations and, ultimately, diverse segments of users. Furthermore, articulations between the multiple subjects of cutting-edge research and its inclusion within education and learning institutions must be encouraged, e.g. at public and private universities, polytechnic courses and grammar schools.

Tourism communication via mobile devices

A recent controversy: tourism communication is more and more conducted using *digital mobile devices*, through the so-called electronic and internet-based *e-tourism* and the more mobile oriented *m-tourism* (Egger, 2010, 2011). After all, mobile devices contribute not just to change culture, as stated here in the section on mobile cultures, but also to transform communication itself. New types of social relations emerge from the use of cell phones in all realms of everyday life. For example. a new literacy results

from the combination of textual features of mobile phones to the use of, say, its ringtones. Moreover, a clear dialectic emerges between two articulated processes, that aren't always consensual: on one direction, outstanding technologies become suddenly ordinary and even necessary, as the use of cell phones by all social classes, which is often judged as an aberration of everyday communication. Inversely, ordinary technology often seems mysterious or discussable, e.g. the belief that mobile phones can communicate with the dead, in some regions of Africa and Asia (Katz, 2008).

Solution / recommendation: more studies must be pursued on the utilization of different or opposite opinions, about mobile devices by tourists, within diverse contexts across various destination places, and inside specific situations where communication happens among tourists and local citizens (Lew, 2004; Meng, 2005; McWatters, 2009; Nyerges, 2011; Perkins, 2011; Paganoni, 2015). For instance, case studies and theoretical research on mobile cultures influencing physical or digital interactions during multiples types of tourism: mass tourism, beach tourism, mountain tourism, eco-tourism, cultural heritage tourism, creative tourism, etc.

Broader solutions

It is not feasible to enunciate here all the possible applications of mobile culture into tourism communication. Thus, just some broader considerations including possible trends and respective solutions will be stated below.

We noticed that mobile digital information, knowledge and culture are more and more produced and consumed within multiple and diverse locations of cyberspace, e.g. at sites, wikis, virtual museums etc. And nowadays this is done, extensively and intensively, through mobile devices. These appliances disseminate different configurations of digital information, knowledge, culture and arts, according to the subjects and means of expression implemented in its apps, among other factors.

Cyberspace and cybertime

In order to understand this new social and cultural conjuncture, it is necessary to note the following. Cyberspace, circumscribed by William Gibson (1984), does not exist without cybertime (Andrade, 1996). *Cybertime* is a social process and concept defined as a set of temporalities browsed by Internet users, such as the synchronous rhythm of a chat, an almost synchronous beat of a social network, or the asynchronous rate of a web page. The societal and conceptual constellation cyberspace / cybertime hosts a number of new institutions, organizations, associations and groups, e.g. virtual museums and galleries, which constitute new places of production, exhibition, sharing and criticism of digital culture, knowledge and arts (Parry, 2009).

Web 2.0 and Web 3.0

Among other virtual localities, the user travels across *Web 2.0* (or Social Web) dispositives such as the social network Facebook, or along *Web 3.0* (Semantic Web) instruments e.g. Wikipedia. *Web 2.0* means the so-called second age of the internet, which had a notable development after 2001, and where users became apparently more active than in the precedent decade. In other words, in addition to reading information, they also write content, e.g. posts and comments in blogs, or messages to other users within social networks. That's why *Web 2.0* is also named '*reading/writing Internet*'. *Web 3.0* consists of a network mode, which is censed to foster a new style of reception and production of information,

knowledge and meaning. It is often nominated *Semantic Web*, because its main aim is to construct social semantic sites and networks where their own underlying model of meaning and knowledge is manifest and described (Andrade, 2011).

FUTURE RESEARCH DIRECTIONS

Finally, in this section, some emerging directions and opportunities of research are reported, in order to progressively test the viability of the corresponding paradigms.

Virtual, Augmented, Mixed and Hybrid Realities

In these last years, mobile phones have been enabling applications including some articulation among different reality modes, configurations or constellations. For instance, virtual reality allows immersion of a user into virtual worlds, while augmented reality blends some virtual objects or scenes with physical or social reality. Mixed reality means a fusion of virtual and augmented realities. Beyond this, *Hybrid Reality* transforms the very nature of media involved in a given process. In other words, originating or originary (initial) media will be mutated into original (new, innovative) media.

In this perspective and paradigm of multiples realities, apps may target consumer profiles such as youngsters and tourists: i.e. they can show real locations in images, video, or 3D, and real-time information or knowledge about them. This trend inaugurates an *augmented / hybrid urban culture* and an *augmented / hybrid tourism*, where the reality of leisure (free time from working hours) is enhanced or blended by the combination between (a) spectacular entertainment and (b) relevant information or knowledge on places visited and on cultural events.

Worldwide cities have been supporting such intelligent development strategies for mobile societies and cultures, e.g. through programs UNESCO Creative Cities and Smart Cities. And research will find here proficient opportunities to develop innovative reflections and novel applications to multiple economic, social and cultural uses.

BRIEF CONCLUSION: MOBILE TOURISM COMMUNICATION, A NEW FORM OF ACTION AND KNOWLEDGE?

The preceding sections circumscribed the main issues and debates on the subjects in question. Some concluding remarks are the following:

Firstly, mobilities, mobile cultures and tourism communication, not just constitute recent and somehow unexplored networks of *mobile social practices*. They also emerge as webs of subjects in constant *reflexive mobility*, convoking multiple areas of information and knowledge, such as economy, management and social sciences.

Secondly, such perennial movement of practices and discourses circumscribes a specific *style of tourism communication*, which is becoming not just *intercultural* in the confluence of citizen and tourist cultures, but more and more a somehow *hybrid communication*. This means that communication in the area of tourism is using different instruments and methods, that are blended in order to organize and do the management of diversified and complex contacts, decisions and messages shared and exchanged among the stakeholders involved in tourism activities.

Thirdly, this hybrid nature of mobile tourism communication, may constitute pertinent reflections within new *savoirs*, such as *Hybridology* (Andrade, 2015). This term means the interpretation of all kinds of hybrid entities, within our interconnected world, which shares, mix and fusion all local and global processes, structures, contexts, events, actions, subjects and objects.

In sum, all conclusions proposed inside this mobilities realm are, so far, inconclusive. Therefore, the present text just intended to furnish some clues to the possibilities, but also to the limitations, of this mobile debate on contemporary social processes such as mobile culture for tourism communication, that are irreversibly mobilizing and transforming our contemporary mobile world.

KEY TERMS AND DEFINITIONS

Citizen: A social actor who inhabits within a democratic society. (S)he may establish pacific or conflictual relations with other city inhabitants or visitors, such as tourists or immigrants.

Cybertime: The rhythms that an internet user activates when s(he) explores digital network's territories within cyberspace.

Hybrid Reality: A fusion of various configurations or constellations of reality, e.g. Mixed Reality and the so-called "Real Reality".

Mixed Reality: This concept signifies a fusion of Virtual and Augmented Realities.

Mobile Culture: A recent mode of production and consumption of information, knowledge and culture, articulated to social mobilities and discourses on the urban, and mainly activated through digital mobile devices, such as cell phones.

Mobilities: In our contemporary world and societies, all processes, capitals, actors, and things, and even spaces and places, are permanently on the move and being transformed.

Tourism Communication: This concept is based on three main modes of communication: (a) *interpersonal face-to-face interactions* among tourists and inhabitants, citizens and immigrants within a physical and social destination place; (b) *classical mediated communication*, undertaken by tourists through tourism institutions (tourism central or local offices), tourism organizations (tourism agencies) and via mass media e.g. newspapers, television; (c) *digital media*, for instance tourism sites and social networks and, recently, digital mobile media. Mobile devices are the main tool that contribute to the emergence of both the so-called electronic and internet-based *e-tourism* and the more mobile oriented *m-tourism*.

Tourist: A social actor, originating in a departure society and culture, that visits destination societies and cultures, within (her)his leisure time.

Web 2.0: The so-called second age of the internet, that had a notable development after 2001, and where users became apparently more active than in the precedent decade. That is, besides reading information, they write content, e.g. posts and comments in blogs or messages to other users in social networks (Facebook, etc.). That's why Web 2.0 is also named '*reading/writing internet*'.

Web 3.0: This network mode is censured to foster a new style of reception and production of information, knowledge and meaning. It is often nominated *Semantic Web*, in that its main purpose is to construct, deconstruct and reconstruct social semantic sites and networks, where their own underlying model of meaning and knowledge is manifest, described, narrated, and interpreted.

The Integrated Tourism Analysis Platform (ITAP) for Tourism Destination Management

Pedro Miguel Gomes

EEA Grants Unit, Secretary General for Environment and Energy Transition, Portugal

INTRODUCTION

Tourism in the European Union (EU) is the third largest socio-economic activity and the world leader in tourism destinations, making an important contribution to the EU's gross national product and employment. Tourism is an important sector for sustainable local development, by preserving and enhancing cultural and natural heritage. The European Commission estimated that European tourism industries are almost 2 million, most of them small and medium-sized (SMEs), providing work for 5% of the total EU workforce (Juul, 2015).

In the tourism sector, data analytics using information on online platforms are the order of the day, offering results and value conclusions. Even so, according to the literature review (Wong, Law & Li, 2017), the work done so far, has focused on technical aspects of the analytical, and few of them in the tourist management. Of these, a part has focused on understanding the mobility of tourists based on different criteria, such as space, time, and the profile of visitors (Vu, Leung, Rong & Miao, 2016; García-Palomares, Gutiérrez & Mínguez, 2015; Kádár & Gede, 2013; Leung, Vu, Rong & Miao, 2016). And so, understand the relationship between types of attractions and types of tourists or the difference between visitors and residents. Other works have also used the digital track, to make tourist recommendations (Xu, Chen & Chen, 2015; Okuyama & Yanai, 2013; Jiang, Yin, Wang & Yu, 2013; Kurashima, Iwata, Irie & Fujimura, 2013). But only one work (Zhao et al., 2017) has been found that analyzes the images to predict the interests of visitors and another recent work (Cai, Lee & Lee, 2018), which takes into account the factors of space and time sequentially.

Online social networks have features common to several user profiles, such as demographics (location, age, gender, education) and interests (religion, sports, politics, music, literature). Such a profile can act as an integration element with other elements (Boyd, 2008). Features such as updates and comments allow the users to evaluate the content and to serve as recommendations to other users. The metadata gives the possibility to create references such as the Twitter hashtags (#) with titles, descriptions, category and keywords, from which, it's possible to filter or extract information.

The existing opinion extraction systems nowadays are created to analyze the English language and for specific text topics, such as movies or other type of product reviews. More than just evaluating the positive or negative feelings of the sentences, the data of social networks can provide more information regarding particular aspects, for example, tourism. Opinions in social networks have been generally classified according to its polarity (positive or negative) and intensity (number of opinions). Sentiment

DOI: 10.4018/978-1-7998-3473-1.ch113

analysis is a huge step concerning machine learning and the latest trends include the development of routines allowing clarifying the lexical subjectivity of options. The analysis of information from social networks comprehends two main areas: Social Network Analysis and Sentiment Analysis. The first concerns pattern detection for descriptive or predictive relations between the elements of social networks (Curran, O’Kane, McGinley & Kelly, 2010), assuming that these patterns are important parts of the users’ interaction with the real world. It’s known as link mining since not only identifies categories, but also relationships and attributes of the analyzed nodes, from which it’s theoretically possible to predict the node and link connection to other nodes, via neighboring algorithms and even clustering of nodes with common structure. Sentiment Analysis is the text treatment according to the development of algorithms and lists to represent statements as positive, negative or neutral regarding a given topic (Pang & Lee, 2008). The World Wide Web allowed developing more studies in this field, since the production of information led to Big Data. The answer to Big Data was the development of techniques to extract relevant information through the interpretation and classification of contents from websites, blogs, forums, open data portals and social networks, among others. Liu (2010) presented the steps that comprise the sentiment analysis process: extraction of relevant information; identification of objects and features of the referring opinions; classification of sentiments; and visualization.

We intend to combine opinion mining with the geospatial location of a touristic review to enable a context-aware analysis of the ITAP data. Instead of overwhelming the user by showing the details first, we visually group similar patterns together and aggregate them by applying Self-Organizing Maps in an interactive analysis application. Thus, ITAP will be able to cope with unstructured touristic user feedback data and shows location dependencies of significant terms and sentiments. The capabilities of our approach are shown in a case-study regarding “Intelligent Analysis of tourists’ behavior” in Barcelona using real-world user feedback data exploring and describing interesting research questions.

BACKGROUND

Tourism is a phenomenon that reaches social, cultural and economic spheres focused on the movement of people from their usual locations to other places, motivated by personal or professional purposes, such a broad field of study is also a great opportunity to improve the services of Startups (e.g. Travel & tourism Barcelona Startups such as Grandtourgo (2018) or Authenticitys (2018) and of companies specializing in internet-related services and products in the hotel, lodging and meta search fields (e.g. Trivago); and also develop new business opportunities as well as technological evolution. And despite being an unpredictable branch of the economy due to factors such as political instability and natural disasters, Tourism continues to be a growing sector in Global economy with a GDP growth of 4.6%, surpassing the growth of global economy (3.0%), while generating over 8.2 trillion dollars and 313 million jobs in 2017 (Statista, 2018a). Tourism in the European Union (EU) is the third largest socio-economic activity and the world leader in tourism destinations, making an important contribution to the EU’s gross national product and employment (Statista, 2018b).

These figures point out the need to have better information systems for stakeholders or common users. Buhalis (2003) pointed out the necessity of better integrated systems of information and communication to develop the tourism sector and evolving it within businesses and organizations, 15 years later with the advent of big data and real time data, information in the tourism sector is no longer just a necessity, it’s the driving force behind its strong growth.

The role of technology in tourism transformed common travelling into “smart tourism” with the internet becoming the main distribution channel and evolving it to e-tourism (Buhalis, 2003) in a similar framework to e-commerce, where users would access online tools to acquire services and products, increasing the touristic network and thus, increasing the need of specialization of tourism companies. The technological response evolved from the searches via personal computer and the need of time for travel preparation to the current touristic patterns where providing experiences can be made almost in real time with the use of mobile technology, such as tablets and GPS technology.

Smart tourism is the evolution from e-tourism in a sense that data can be collected, shared, stored and analyzed with algorithms to maximize future users’ experiences using the users’ own perception regarding the visiting sites. This new paradigm changes the users’ experiences while creating new business models with new touristic flows, better services, more advertising models and innovation with the association of tourism with other business segments. The application of smart tourism nowadays is more applied to cities in a sense that there’s still a high need of infrastructures, resources and business density to access the required data to achieve efficiency, sustainability and quality of life while developing new ways to create value.

The Integrated Tourism Analysis Platform (ITAP)

The ITAP solution must be presentable for the tourism stakeholders and easy to use for the end users. The end-users will range from specialized researchers studying the tourism fluxes, Public bodies (NSI), tourism agencies or ICT working under the Tourism Directives.

In June 2010, the European Commission adopted the Communication, “Europe, the world’s No. 1 tourist destination – a new political framework for tourism in Europe”. This framework consisted in four major points of action:

1. To stimulate competitiveness in the European tourism sector.
2. To promote the development of sustainable, responsible, and high-quality tourism.
3. To consolidate Europe’s image as a collection of sustainable, high-quality destinations.
4. To maximize the potential of EU financial policies for developing tourism.

Our vision embodies these four points, while providing a contribution in terms of technological solutions, while following the Open Source Vision.

Tourism is an important sector for sustainable local development, by preserving and enhancing cultural and natural heritage. According to the latest data from the Organization for Economic Co-operation and Development (OECD), in OECD Member States, tourism directly contributes, on average, around 4.7% of GDP. The European Commission estimated that European tourism industries are almost 2 million, most of them small and medium-sized (SMEs), providing work for 5% of the total EU workforce (Juul, 2015).

Following the Lisbon Treaty, the European Commission prepared a strategy for Tourism via projects and initiatives to provide mainly financial support for tourism in the EU. The aim is to maintain Europe as a leading destination while contributing for the industry’s contribution to growth and employment with the promotion of cooperation between EU countries (Juul, 2015). The main technological challenges for tourism will consist in “keeping up to date with IT developments caused by the globalization of information and advances in technology (IT tools for booking holidays, social media providing advice on tourism services, etc.)”. ITAP intends also to provide an answer for tourism services using social media.

The Commission promoted several projects and initiatives, such as grants and events (e.g. the annual European Tourism Forum), competitions and webinars (web seminars on e.g. marketing tourism businesses online), websites providing networking opportunities (e.g. www.tourismmlink.eu), studies and surveys (e.g. Eurobarometer reports on the preferences of Europeans towards tourism). There was also promotion to the involvement of SMEs and various tourism stakeholders, such as local and regional authorities. In 2009-11, the EU allocated €1-1.5 million per year for Calypso projects and for 2012, €450 000 (Juul, 2015). The funding for these projects came from the Entrepreneurship and Innovation Programme (EIP), and since 2014, from the Programme for the Competitiveness of Enterprises and SMEs (COSME). In order to develop sustainable tourism, the Commission has co-founded the development of cultural routes that help European as well as non-European tourists to discover how Europeans have lived since ancient times. It has co-funded, for example, the development of a route of astronomical sites in Europe (in Greece, Spain, Italy, Portugal and Bulgaria); such as a long distance EuroVelo route (e.g. the Iron Curtain Trail which invites tourists to discover the former division of Europe on a 6 800 km cycle track along the former border), combining European culture, history and sustainable tourism.

The EU provides support to the tourism business sector in three ways: 1) Digital Tourism, 2) Professional Skills, 3) Enterprise Europe Network. The ITAP solution intends to be transversal to these three aspects, since it's a different technological solution, from which it will be also possible to extract information to have means to improve the professional skills from the users (e.g. locating agencies related to the tourism sector) and to promote brands and businesses related to this activity.

ITAP's Objectives

The main goal is to take advantage of the ENERGIC OD Virtual Hubs and Open Data portals, Mobile, Geotagged city information, Open data, Social media data containing information about touristic events; from ITAP crowdsourcing platform; from sensor conception and existent experimentations, namely the data from the Internet of Things native experimentation (wireless sensor network experiments) and service provision experiments (applications using real-time real-world generated sensor data). In this sense, it was intended to implement an interactive dashboard to integrate and explore different data sources related with tourist management.

ITAP's Architecture

The ITAP solution will be built on the existing scientific and commercial achievements to test the applicability of using Mobile, Geotagged city information, Social media, Crowdsourced and Open data for tourism analysis. Web-based application will be deployed to analyze crowd gatherings, based on an application to detect crowd gatherings from mobile location data automatically. Geotagged city information, Social media, and Open data will be used to add contextual information to tourist movements. The existing sensor networks and experiments will be used to test the effects of various environmental factors on tourism, such as: Internet of Things native experimentation (wireless sensor network experiments) and service provision experiments (applications using real-time real-world generated sensor data).

The ITAP solutions will rely on Big Data Technologies, namely the MongoDB, SparkR and Shiny - RStudio. The use of several large datasets and their integration will push the capabilities in terms of customizability and data processing. In a context of tourism-related big data, we face a challenge of integrating several data sources in different categories: data generated by users including online textual data and online photo data; device data (by devices), including GPS data, mobile roaming data,

Bluetooth data, etc.; transaction data (by operations), including web search data, webpage visiting data, online booking data, etc. Therefore, carrying different information, different data types address different tourism issues in ITAP.

Datasets to be used in the interactive dashboards:

- Data sources integrated in the ENERGIC OD Virtual Hubs.
- Mobile data (e.g. Orange, Vodafone).
- Data from IoT infrastructures: Fixed/Mobile Sensing; Pace of the City; Information Points; Participatory Sensing.
- Geotagged city information about tourism, culture, commerce, transport, sports, events.
- Open Data such as Open Street Maps (OSM) and Open Data portals.
- Social media data for contextual information, such as, Twitter, Facebook, Flickr, Instagram and TripAdvisor.
- ITAP Web-based Crowdsourcing Framework. Includes INSPIRE data together with the crowdsourced data. The crowdsourced data will be structured according the INSPIRE Data Specification on Population Distribution.

Figure 1. Proposed flow diagram of ITAP

The system architecture of the ITAP will include two main components (Figure 1): ITAP Back office and ITAP Front-end modules 1 and 2. The ITAP back office corresponds to a Processing layer / Low-level processing, based on MongoDB and SparkR, where will be performed data curation, pre-processing of the raw data (structured, semi-structured and unstructured) and implementation of machine learning models for opinion mining. All datasets, according to geospatial according to the Open Geospatial Consortium (OGC), will be collected with data collectors in order to be harmonized and stored in a standard format (GeoJSON). Concerning the Opinion mining, we intend to implement a novel method in the RSpark framework. The algorithms will exploit the hashtags and emoticons as sentiment labels, and proceeds to a classification procedure of diverse sentiment types in a parallel and distributed manner.

The ITAP front-end module 1 and 2, based on Shiny - RStudio, will allow the users to explore data analytics and interactive visualizations of the distinct data sources. The ITAP front end module 1 will allow the Spatio-Temporal Data Analytics, Social Network Analysis and Sentiment Analysis with the geospatial location. The second module of the ITAP interactive dashboard will be used to display the relationship between the local attractions (events, cultural venues) and the foreign visitors in a visual immersive way. We expect to achieve unusual results with strong visual representations accessible on location.

Discussion

Knowing the tourists' behavior is very useful for tourism destination management when planning territorial and marketing strategies, however, it is also of interest, for those tourist information platforms, when making suggestions in person. The ITAP tool could be valuable for projects related with "Intelligent Analysis of tourists' behavior".

In this kind of case study, it is intended to analyze and know intelligently, what is the visitors' behavior and the criteria for decision making regarding their trip. In order to achieve these objectives, visitors' information can be analyzed, such as knowing their destination, the typology of visited sites and the emotions expressed during the travel. The sources of information will be TripAdvisor, Instagram and data of mobile phones.

In order to strengthen the information, it will be used Artificial Vision technologies to detect the typology of activities carried out by the tourists, as well as the location. Machine Learning, Deep Learning and Natural Language Processing algorithms will be applied to extract emotions from the social networks publications.

It is expected that the combination of these sources and with the use of the ITAP tool, the extraction of information can solve questions, such as:

- What is the interest of a certain area and how much time is it spent on it?
- What are the areas with the lowest satisfaction levels? And the ones with greater satisfaction?
- What are the routes that generate the most satisfaction?
- What are the most visited areas, that generate fewer publications?
- What is the relationship between the types of activities carried out during the morning and those made during the afternoon? And the activities that are done during the year with those that are made during the holiday period?
- Which tourists will repeat the visits? What are you interested in? What other tourist destinations will you visit?
- Where do the visitors generate a positive satisfaction?

FUTURE RESEARCH DIRECTIONS

Interactive decision-support tools, such as ITAP, have become an essential tool in outcomes improvement for integrated tourism analyzes. They can provide important insights and near real-time data, helping touristic destination managers and citizens make better decisions about tourism events and patterns. Today, decision-support tools are evolving beyond traditional dashboards into true real-time reporting and customizable self-service tools that meet the ever-growing demands of tourism data.

In the next steps, we plan to extend the data source catalog with more private data, and implement a new module integrated in the ITAP Dashboard in which citizens and policy makers can share and co-create personalized visualizations. Therefore, with the ITAP integrated dashboard, we intend to present a new and comprehensive way of enabling citizens to define and adapt tourism-related real-time data visualizations by themselves. Instead of relying on pre-packaged solutions that can only address restricted and communal needs, we enable and touristic destination managers and citizens with little or no expertise to create their custom visualizations taking advantage of the provided functionalities in ITAP Front-end modules 1 and 2.

CONCLUSION

With ITAP will be easy to use and provide near real-time data about tourism events and venues linked to social media data, Open and Crowdsourced data, geotagged and sensor city information related to environmental aspects, and users and touristic destination managers can have access to the deep insights in their data and can use the knowledge to drive improvement initiatives.

In this sense, ITAP leads to the definition of many key aspects to building a good decision-support tool. The following five features are essential to implement this interactive decision-support tool:

- Be easily accessible: A decision-support tool should be easily accessible to each user who will need to tap into its insights.
- Display reliable data: Users need reliable, trustworthy data.
- Contain relevant data: A good decision-support tool should only contain the factors users need.
- Use timely data: A decision-support tool needs to contain near real-time data, so users can address challenges promptly.
- Include trends and/or benchmarks: Trends and benchmarks show users where they've been and where they are going. This retains them involved and motivated.

KEY TERMS AND DEFINITIONS

Big Data: Mainly was used as a term to define a large or complex volume of structured, semi-structured and unstructured data that can be mined for information and used in machine learning projects and other advanced analytics applications.

Crowdsourcing: Obtaining information's or inputs by enlisting the paid, or normally unpaid services of a large number of people, typically via internet.

Data Analytics: Discovery, interpretation, and communication of meaningful patterns in data; and the process of applying those patterns towards effective decision making.

ITAP: Integrated Tourism Analysis Platform.

Natural Language Processing: Sub-field of Artificial Intelligence that is focused on enabling computers to understand and process human languages, to get computers closer to a human-level understanding of language.

Sentiment Analysis: The process of computationally identifying and categorizing opinions expressed in a text, especially in order to determine whether the writer's attitude towards a particular topic is positive, negative, or neutral.

Smart Data: Formatted digital information so it can be acted upon at the collection point before being sent to a downstream analytics platform for further data consolidation and analytics.

Social Network Analysis: Process of investigating social structures through the use of networks and graph theory.

Exploring Terroir Zone and Tourism Cluster Based on GIS Mapping

10

Ya-Hui Hsueh

National Taichung University of Education, Taiwan

INTRODUCTION

Terroir in term of agro-viticulture at the plot scale demonstrates significant differences of grape varieties, rootstocks and soil management practices in which different degrees of variability of environmental factors. Terroir related to agro-viticulture primarily focuses on the relationships between environmental factors related to vines, the quality of grapes and wines in order to assess the potential of vineyard quality and the indigenous knowledge in the defined area (Goulet & Morlat, 2011). Terroir is a spatial, ecological and cultural concept that links the cultivators with the special agricultural practices (traditional knowledge and cultivating technology), and it focuses on environment factors such as terrain, soil and climate conditions. Terroir conveys geographical distinctiveness, culture identity of a collective memory and a framed place name against globalization food production (Bowen & Zapata, 2009).

Even the agricultural products are not cultivated on a terroir zone, the linkage between agriculture and tourism is still evident. The nature of agricultural products, availability of other supporting cultural and tourism products, and proximity to markets vary from place to place. These factors influence the form and strength of links that can be fostered between agriculture and tourism. Stratford and Muskoka, both at a similar distance from metropolitan Toronto with strongly seasonality in their agricultural products and tourism, demonstrate different extent of agriculture linkages with tourism. Stratford with possessing more productive farmlands has a much stronger agricultural resource base than Muskoka, while Muskoka has longer history for tourism development based on the forested-lakes complex. Although neither of Stratford and Muskoka has the reputation to claim status as a “terroir” in the absence of a specific place branding strategy, both have successfully developed culinary tourism by the linkage of agriculture and tourism (Lee, Wall & Kovacs, 2015).

The Niagara Region has become home to an emerging New World Wine Route by the competitive advantages of winery clusters on the increasing in scale for marketing is the horizontal cluster advantage of the wineries surrounding the heritage-shopping town of Niagara-on-the-Lake. The complementary to the wineries of close to 60 tourist shops, numerous accommodation establishments, a historic fort and a festival theater reveals the advantage of tourism cluster. At the Regional level, the entire Niagara Wine Route with over 50 wineries, which are connected to the major tourist attractions of Niagara Region. Label of origin is particularly useful for the embeddedness and convention for marketing terroir specialties. By insisting upon a strong link in production to the ecology and culture of terroir, a local brand in the natural process labeled by terroir is essential. Several destinations and festivals promote their terroir specialties to serve as major tourist foods (Telfer, 2001).

A viticultural terroir is related to a particular area with a distinct quality of grapes and their wines in France. Although the conception of terroir is used as an analysis unit for comparing chemical composition of vintage products in different viticultural zones (Schlosser, Reynolds, King & Cliff, 2005; Bonfante, Basile, Langella, Manna & Terribile, 2011; Bowen & Zapata, 2009). Terroir means a small

DOI: 10.4018/978-1-7998-3473-1.ch114

area of land reveals characteristics of a cultivation zone, an environmental complex including conditions of terrain, climate, and soil. Terroir related researches have mostly focused on the relationships between the quality of grapes or wines and a few environmental factors for the past 30 years. Until 1990s, GIS mapping was used on the concept of terroir by focusing on spatial analysis of diversity of viticultural environments in different areas (Vaudour, 2002). Thus, there is a need for empirical research on a better meaning of linkage between terroir and tourism by using GIS mapping to define terroir zone and its impacts on tourism cluster. This chapter aims to define different agricultural terroir zones, analyze the influencing factors on the spatial distribution of terroir zones by processing GIS mapping to examine the role of terroir specialty on how to shape a tourism cluster.

Although the linkage between agricultural products and tourism was weak on the food supply chains of hotel service sectors, the development of tourism itself does not trigger decline of agricultural sector, and the demise of agriculture can be attributed largely to the emergence of tourism as a viable alternative to a chronically unstable agricultural sector. Actually, the linkage between agriculture and tourism plays an importance role on the dimension of tourism development. When tourists are seeking authentic and unique experiences, agricultural products bring tourists in close proximity to the host culture, which can be as an input to tourist attractiveness. Foods and beverages have long been regarded as important components of tourist experiences, often can promote destination image and as contributors on festivals. Regarding to travel motivation, foods and beverages range from high interest to a destination as the primary motive to visit a specific restaurant or winery by accidental discovery (Plummer, Telfer, Hashimoto & Summers, 2005).

Terroir specialty, in relation to tourist food, sustains cultural heritage, promotes destination's visibility, especially for a significantly larger proportion of peak season, and offers a destination a longer, more sustainable to sell local produces (Everett & Aitchison, 2008). Local specialty referring to visitation of food festivals, restaurants or specific locations for food tasting, experiencing the attributes of cultivation region may be as a primary or secondary tourism motivating factor. Accordingly, terroir specialty can be transformed as a manifestation of tourist food by tasting local food or visiting local food consumption spaces such as restaurants and coffee shops, which become the places of culture performance, rather than simply physical consumption.

BACKGROUND

A number of researches use GIS mapping to define meaningful areas according to different given indexes. Hsueh (2013) defines a clustering area of locations of mushroom huts based on GIS mapping according to the indexes of environment complex of slope, elevation, ventilation and water supply. Hsueh & Chen (2015) use GIS mapping to distinguish a clustering area of locations of tea processing firms distributed on a tea specialized cultivation area to confirm the co-location concept of industry cluster according to the indexes of environmental complex associated with accessibility, climate conditions and terrain conditions. Hsueh & Hsieh (2017) use GIS mapping to clarify a clustering area of pineapple dining industry including pineapple bakeries, creative restaurants and pineapple vendors based on point density analysis, buffer analysis and overlay analysis according to the indexes of terroir zone, tourism cluster, climate conditions, terrain conditions and local practices. Hsueh & Chang (2017) use GIS mapping to define a tourism potential area with ranked scores according to the site criteria of elevation variation, slope diversity, proximity to water, accessibility and service facilities. Hsueh, Chuang & Hsieh (2018), based on GIS mapping, explore a clustering area of tourist spots in a peripheral mountain area to develop

niche tourism in consideration of the linkage between organic agriculture and tourism, creative knowledge and religious attractiveness. Obviously, GIS mapping performs well for defining the clustering area of tourism development, especially on the linkage between agriculture and tourism by overlaying the locations of agricultural farms and tourist spots.

DEFINING TERROIR ZONE BASED ON GIS MAPPING

Taiping District, in the eastern part of Taichung City, is famous for a number of agricultural products, especially as the birthplace of loquats of Taiwan for a long cultivation history. Loquat, cultivated in Taiping District about for 257 hectares, is a kind of high-value cash crops, and the production season ranges from February to April. The climate condition of Taiping is foggy frequently and the temperature varies greatly between day and night, suitable for planting loquats. To promote loquats and other agricultural products, Taiping government holds a series of festivals and events in each year, especially featuring the Bamboo Festival, Lychee Festival and Loquat Festival to market the year's best loquats, bamboos and lychees. Figure 1 illustrates Taiping's terrain condition of elevation altitudes including several hill areas including Shan-Ding-Hill, Jiu-Tong-Hill, Tou-Bie-Hill, Jin-Zi-Dong-Hill, Che-Long-Hill, Da-Jian-Jiao-Hill, and Da-Hen-Ping-Hill. Figure 2 shows the spatial distribution of the three main agricultural products of Taiping District by using GPS positioning the sets of points of locations of 80 loquat farms, 300 bamboo farms and 1650 lychee farms to specify on the GIS raster surface.

Figure 1. Terrain condition of Taiping District

Figure 2. Spatial distribution of loquat farms, bamboo farms and lychee farms in the District

GIS point density analysis can be used to examine spatial clustering of creative industries by locating the sites of creative industry parks and visualize the core area of creative industries clustering (He & Gebhardt, 2012). To define the terroir zone in the District, this chapter also uses GIS point density analysis to sum up as the clustering area of cultivation of different terroir specialties including lychee, loquat and bamboo (cell value 300x300 meters, searching radius 500 meter). Point density analysis is suitable for defining a clustering core or concentration zone of several layers on which each layer is with a set of points. Point density analysis is based on estimating the quantity of points per cell on each neighborhood of a defined searching radius. The harvest season of loquats in the District is in March and April. Loquat tree is wind and drought tolerant, but sensitive to temperature condition, adapted to a subtropical to mild temperature, tolerate temperature as low as 15°C without damage. The killing temperature for the flower bud is too cold below 10°C, and for the mature flower is above 35°C of high heat. The climate condition of high heat above 35°C and sunlight during the winter often results in sun-burned fruit. Loquats grow well on a variety of soils from sandy soil to heavy clay and even limestone soil. Slightly acidic soil with pH range of 5.6 to 6.8 is considered optimum for loquat cultivation. The soil in Taiping is sand shale soil well to be drained and light in texture.

Based on GIS mapping, the loquat terroir zone as illustrated in Figure 3 is consist of 5 loquat specialized cultivation areas including Da-Hu-Tong cultivation area, Luo-Tuo-Keng cultivation area, Nei-Xian cultivation area, Jiu-Tong-Hill cultivation area and Ta-Hu cultivation area. Most of the loquat cultivation areas in the District are located on high elevation hills, and it also reveals that the suitable elevation for

Figure 3. Loquat terroir zone in the District

loquat cultivation is over 500 meters, cold temperature for loquat growth. Figure 4 indicates that the area with the highest point density value between 16.97652691~25.46479034 is located on Da-Hu-Tong cultivation area, the next are Ta-Hu cultivation area and Nei-Xian cultivation area with point density values between 8.488263449~16.9765269, so Da-Hu-Tong cultivation area, Ta-Hu cultivation area and Nei-Xian cultivation area are the 3 significant loquat cultivation areas in the District. Actually, the original loquat cultivation area was located on the Tou-Bie-Hill area in the District in the early stages, but the elevation of this area is below 500 meters not suitable for cultivating loquats due to its heat condition, so the loquat farmers move to high elevation hills of over 500 meters to cultivate loquats. Although Tou-Bie-Hill area was well known for loquat cultivation and there is no loquat farm now, the loquat origin of place brand of “Tou-Bie Loquat” is still the favorite in Taiwan.

The harvest season of bamboo shoots for eating in the District is from March to November. Bamboo is suitable to grow in the climate conditions of high temperature and high humidity, adapted to the terrain of elevation below 500 meters. Bamboo shoots grow well on a sandy soil with slightly acidic soil of pH 7, and the soil in Taiping is sand shale soil well to be drained and light in texture. Based on GIS mapping, the bamboo terroir zone in the District is illustrated in Figure 5, which is consist of Shan-Ding-Hill cultivation area, Che-Long-Pu cultivation area and Nei-Xian cultivation area. Most of the bamboo cultivation areas in the District are located at the elevations below 500 meters, and it also reveals the suitable climate condition for bamboo cultivation is high temperature. Figure 6 indicates the areas with the highest point density value between 39.04601289~58.56901932 are located on Shan-Ding-Hill cul-

Figure 4. Point density analysis of locations of the loquat farms in the District

tivation area and Che-Long-Pu cultivation area, 2 significant bamboo cultivation areas in the District. Actually, the most famous bamboo in the District-King bamboo is cultivated in the Che-Long-Hill area, but this kind of bamboo is rare, not easily available to pick and grows on steep slope, so this bamboo also called “beheaded bamboo” to describe the risk to bamboo farmers. Beheaded bamboo has been described as “King of bamboos” because of its flavor difficult to find. Due to the delicious and the fresh, Taiping bamboo is popular for cooking a variety of creative cuisine. Annually, Taichung City holds Taichung Bamboo Competition for marketing bamboo, and Taiping bamboo often wins the championship in the competition, thus Taiping bamboo is branded with the origin of “Golden Bamboo”.

The harvest season of lychee in the District is in June and July. Lychee, similar to bamboo, is also suitable to grow in the climate conditions of high temperature and high humidity, adapted to the terrain of elevation below 500 meters. Lychee grows well on a sandy soil with slightly acidic soil of pH 5.0 ~ 5.5, and the soil in Taiping is sand shale soil well to be drained and light in texture. Based on GIS mapping, the lychee terroir zone in the District is illustrated in Figure 7, which is mainly including Shan-Ding-Hill cultivation area and Che-Long-Hill cultivation area. The 2 significant lychee cultivation areas both are located at the elevations below 500 meters, and it also reveals the suitable climate condition for lychee cultivation is high temperature. Figure 8 indicates the area with the highest point density value between 117.9868674~176.9803009 is located on the Che-Long-Hill cultivation area. Actually, the most famous lychee in the District is nuomici lychee cultivated in the Tou-Bie-Hill area, also called “Queen of lychees” to describe the special flavor of juicy and delicious. Due to the fragrant and the sweet, Taiping lychee is

Figure 5. Bamboo terroir zone in the District

Figure 6. Point density analysis of locations of the bamboo farms in the District

Figure 7. Lychee terroir zone in the District

Figure 8. Point density analysis of locations of the lychee farm in the District

popular for cooking into dishes as ingredients of a variety of creative cuisine. Annually, Taichung City holds Taichung Lychee Competition for marketing lychee, and Taiping lychee often wins the championship in the competition, thus Taiping lychee is branded with the origin of “Golden Lychee”. Combined with Figure 4, Figure 6 and Figure 8, the common terroir zone of loquat farms, bamboo farms and lychee farms can be distinguished to be from Che-Long-Hill through Shan-Ding-Hill to Nei-Xian hill area.

THE LINKAGE BETWEEN TERROIR ZONE AND TOURISM CLUSTER

A positive linkage between tourism and agriculture is demonstrated on the Spanish coast which indicates that tourism has been the motor for the development of agriculture in Cambrils (Hermans, 1981; Torres, 2003; Berno, 2011; Everett & Slocum, 2013; Kim & Ellis, 2015). According to Bowen, Cox & Fox (1991), tourism is supposed to regenerate agricultural production regions with gastronomic tastescape that draw on charming concept of pursuing purity and landscape. Socher & Tschurtschenthaler (1994) categorize agriculture to two dimensions of supply for tourism-direct supply, which involves the sale of agricultural products to tourists, and indirect supply, which involves agricultural landscape preservation as tourism resource. Accordingly, symbiotic relationship of agriculture and tourism is demonstrated on the classification scheme developed by the analysis of agricultural sector shaping leisure attractions on three main components: cuisines, tours, and leisure activities. Local creative cuisine can be distinguished by offering different tasting flavors as a pull force of tourist attractions. Traditional agricultural production region is transforming its nature essence to visitors, negotiating a balance between the daily operation of business and demand for new experiences of tourist consumption. When the agricultural production region is simultaneously the consumption space of landscape and leisure activity, the living space of arable land for farmers is also transformed to destinations for travelers (Everett, 2012; Rogerson, 2012).

The linkage between tourism and agriculture reveals the complex of terroir zone and tourism cluster by enhancing the supply of local agricultural products to promote the terroir specialties. On the dimension of how to transform terroir specialties to tourist foods, festival activities play an important role. In an effort to increase the consumption of tourist foods, regular meetings held between government sectors, agricultural associations and tourism related sectors example for restaurants and B&Bs. Consequently, the restaurants serving local creative cuisines, B&Bs offering beautiful scenery and popular tourist spots with historical culture are combined together to promote Taiping tourism by holding several festivals during a year regularly such as Taiping Loquat Festival and Taiping Lychee and Bamboo Festival. Figure 9 illustrates the obvious tourism cluster in the district, especially in Route 136 a number of restaurants, B&Bs and tourist spots cluster here providing a competitive advantage for the tourist foods and landscape sceneries. Route 136 is an important access of tourism cluster, along it many vendors for the sales of loquats, bamboos and lychees in different production seasons based on the place brand of “Taiping”.

Taiping’s festivals including Loquat Festival on March, Lychee Festival on June and Bamboo Festival on July not only help marketing terroir specialties but also allow tourists to experience the agricultural landscapes and appreciate the terroir zones. Taiping Depth Travel Center, Taiping Farmer Association and several local associations cooperate to market Taiping tourism with the linkage established between tourism cluster and terroir zone. Tourism promotion can focus on tourist foods which may stimulate terroir specialty demand, while agricultural promotion may focus on picking activity and lead to a growth in tourism, thus terroir specialty and tourism combine to link symbiotic relationship. Annual Taiping loquat, bamboo and lychee Festivals celebrate the terroir specialties by holding creative cuisine competitions well-known for providing creative cuisine of healthy, tasty and colorful dishes. While the festivals

Figure 9. Tourism cluster of tourist spots, B&Bs and creative cuisine restaurants

hold, a number of brochures present “creative cuisine served as loquat wine, loquat fish, loquat chicken, loquat sea food and loquat dessert combined with loquat sightseeing bus tour” to attract tourists. The restaurants contribute to promote the linkage between agriculture and tourism by providing creative cuisines, such as loquat wine baked fish, bamboo steamed fish, bamboo baked duck, lychee sweet and sour fish, as well as lychee salmon roll. A living expression of the concept of terroir refers to an area or terrain, usually rather small, a marked influence on its inhabitants believing in rooted terroir customs or idioms of interplay of human ingenuity and practice with the native place (Barham, 2003). The creative cuisines on the festivals reflect the involvement of powerful social actors, such as farmer’s associations on how to make the transformation from terroir specialties to high quality tourist foods.

In addition, Taiping’s tourism cluster not only is confined to the Route 136 but also concentrates in the loquat, bamboo and lychee terroir zones. As evident in Figure 9, several restaurants, B&Bs and tourist spots cluster in the Jiu-Tong hill area, Che-Long hill area and Shan-Ding hill area, which specify the appealing of place characteristics as well as tourism potential by holding creative cuisine festivals. On the festivals, Loquat and Lychee Tourist Bus offers various creative cuisine itineraries of package tours to visit different terroir zones for picking loquats and lychees as well as dropping off and picked up in front of the creative cuisine restaurants. In 2017, a package tour of “Loquat Tourist Bus” is promoted for experiencing the “loquat package meal” including Oxbow Lake Story Island restaurant’s lychee kiln pizza, Taiping Depth Travel Center’s loquat pineapple baked shrimp and loquat sauce ribs, Gao-Chao-

Sen-Huo restaurant's loquat package meal, Yuan-Jung 136 Coffee restaurant's loquat roasted chicken and La Fatte's loquat roasted chicken and loquat baked lamb chops.

Four factors mainly determine the style of Taiping creative cuisine are government support, terrain, climate condition and making practice. Especially, making practice is the primary factor to determine the style of creative cuisine based on the indigenous knowledge on the dimension of how to cook dishes and turning terroir specialties to tourist foods. The tourism cluster of tourist spots also stimulates the demand of creative cuisines, the transformation of terroir specialties to tourist foods, and the providing places to pick agricultural products. The loquats, bamboos and lychees in the District are consumed fresh, baked, juiced or preserved in a wide variety of creative cuisines such as crushed loquats or lychees for jam, vinegar, enzyme and ice cream. The Wine and vinegar, which is made by fresh loquats or lychees, are served as beverages. The Chunks of loquats bamboos and lychees are also can be preserved as conserves. The Loquat or lychee jam can be filled to bread or cake as an ingredient. As the famous agricultural terroir zones, there are plentiful loquats, bamboos and lychees to cook dishes for creative cuisine in the District, thus the restaurants, B&Bs and vendors are flourishing to promote tourism along the main access of Route 136 in the District.

Terroir specialty can be transformed into tourist food, place identity of a collective taste memory and the level of perception of know-how in terms of timing of the growth cycle by demonstrating the characteristics of environmental complex. Tourism cluster in the District is relation to the geography proximity of locations of tourist spots, B&Bs and creative cuisine restaurants. The B&Bs and creative cuisine restaurants dedicate to make creative cuisines to celebrate the loquat, bamboo and lychee festivals. The festivals attract a number of visitors for tasting the creative cuisines featuring the best quality, seasonal and fresh ingredients from the terroir specialties. A famous creative cuisine restaurant-La Fatte, located at the elevation of 750 meters in the Jiu-Tong-Hill area is famous for taking Taichung city night view. The creative cuisines of La Fatte has expanded to more than making delicious dishes-fresh fish with loquat brew and lychee scallops garlic shrimp, in step with creating fantastic desserts such as lychee loquat pizza to emphasize stronger linkage of cuisine and terroir.

Several restaurants also offer a variety of loquat, bamboo and lychee creative cuisines in the district such as Bambino restaurant's bamboo soy-stewed pork and pickle cabbage bamboo, Peng-Cheng-Tang restaurant's bamboo soy-stewed pork, Lin-Ji restaurant's bamboo chicken, Xin-Tai-Ji-Dian restaurant's king bamboo sesame chicken, A-Lang restaurant's bamboo shrimp roll, Yan-Yang-Lou restaurant's lychee bamboo sea food, Gao-Chao-Sen-Huo restaurant's tenderloin loquat roll and loquat duck breast, Oxbow Lake Story Island restaurant's aloe loquat, and Yuan-Jung 136 Coffee restaurant's loquat coffee chicken. Apparently, loquat, bamboo and lychee have been transformed to tourist foods in supporting the development of a myriad of related products on festivals. Indigenous dishes provide tourist attractions of terroir specialties as a symbol of place brand based on the visibility of creative cuisines, which confirm the distinctiveness associated with the terroir zones.

The cycle of peak tourist season and the harvest time of agricultural products of loquats, bamboo and lychees are synchronous in the District which reveals the tourism potential of terroir specialties, which can become tourist attraction by offering terroir-related cuisines or souvenirs. Annually, the food trail of Route 136 from Yi-Jiang Bridge to Chi-Kan-Ding feature the terroir specialties of loquats, bamboos and lychees on the harvest seasons due to the geographical proximity of a number of vendor's cluster. Similar to the concept of terroir of French, the demarcation of terroir zone according to the climate, terrain and soil conditions, the loquats, bamboos and lychees are appreciated for the distinctiveness and flavors. Due to Route 136 can link loquat terroir zone, bamboo terroir zone and lychee terroir zone efficiently, this route has become a famous food trail to buy fresh loquats, bamboos and lychees

Figure 10. A number of vendors cluster along the food trail of Route 136

in different harvest seasons. As evident in Figure 10, a number of vendors cluster along the food trail of Route 136, especially in the section of Yi-Jiang Bridge to Chi-Kan-Ding accounting for 38 vendors. The food trail of Route 136 from Yi-Jiang Bridge to Chi-Kan-Ding is also called “136 cycling Route” due to the characteristics for climbing training of cycling with hairpin turns, accessible from Taichung City, and a series of rising gradients in the last section. Along the food trail, a lot of vendors cluster here has translated the “terroir zone” to a new flourishing “tourist zone” by providing tourist foods related to loquats, bamboos and lychees.

Although there is a process of globalization, tourist foods create greater demands on special local foods and indigenous cuisine (Torres, 2002). Tourism provides the opportunity for direct and indirect linkages with local agriculture and economic benefits derived from tourism in destinations by increasing the number of tourists, the stay duration of tourists and the tourists’ expenditures. A complementary way to promote tourism is to expand the economic linkage by increasing the amount of agricultural products available for sale (Telfer & Wall, 1996). Taiping’s creative cuisines from its terroir zones stimulate Taiping’s tourism cluster. By holding several festivals to market Taiping loquats, bamboos and lychees, Taiping creative cuisines attract a number of tourists to visit (Figure 11, Figure 12, Figure 13, Figure 14, Figure 15, Figure 16), and the creative cuisine restaurants are co-located nearby the terroir zones to take the advantages of spillover effect of tourism cluster and information exchange on the practices of how to make creative package terroir meals.

FUTURE RESEARCH DIRECTIONS

Future research can focus on the relationship of creative cuisine and place brand with advanced aspects on tourism development to identify the importance of terroir zone, including terrain and climate conditions for agricultural products. Implementation of food tourism by marketing specialty and place brands on the aspect of integration of agriculture sector have not reached their maturity to evoke the implication of creative cuisine and terroir zone. Future research and development efforts in the direction also can be demonstrated on the research aspect of “food trail” for its geographical proximity of various specialties and tourism cluster.

CONCLUSION

The linkages between tourism cluster and terroir zones offers in the promoting creative cuisines transformed from local specialties to tourist foods in relation to tourist attractions that feedback the demand of agricultural products. For the local farmers the primary change is the increasing relevance of tourism cluster of tourist spots, restaurants and B&Bs which can offer a combination of local making practices of creative cuisines and the landscapes of agriculture. The creative cuisines of loquats, bamboos and lychees

in the District is characterized by a distinguished design in contrast to other places to take advantage of terroir zones that bring fresh agricultural products baked or cooked by local favorite ways as tourist attractions. The implication of tourism cluster in the terroir zone demonstrates how terroir specialty contribute to the success of tourism on offering creative cuisines with special flavor and promoting the tourist spots for experiencing landscapes. In order to promote the visibility of the terroir specialty, the local restaurants and B&Bs establish additional alliances with other local service sectors such as farmer organizations, farmer markets as well as souvenir shops to enhance tourism development.

Based on GIS mapping, the significant terroir zones not only are clarified but also the primary factor determining the spatial distribution of cultivation areas are examined in terms of terrain conditions. While the linkage of terroir zone and tourism cluster is established, the farmers and local service firms will have a much stronger forces to promote tourism and transform terroir specialty into creative cuisine. The significance of place brand of terroir zone increases an opportunity to promote a new form of tourist food in tourism marketing by tourism cluster combined with the route of food trail. Defining the characteristics of terroir zone aims to further realize the implications of tourism cluster and the formation of tourist zone, which offers and labels of creative cuisines such as loquat package meal, bamboo package meal as well as lychee package meal.

KEY TERMS AND DEFINITIONS

GIS Mapping: A mapping way to define meaningful areas by spatial analysis according to different given indexes for the representation of a set of points, lines, or areas data.

Terroir Zone: A zone defined by the special agricultural practices of traditional knowledge and cultivating technology related to the environment factors such as terrain, soil, and climate conditions.

Tourism Cluster: A confined area related to tourism development including tourist spots and tourist service facilities such as restaurants, accommodations, and traveler centers.

Tourist Food: A local food with place brand to experience a place culture rather than simply physical consumption for travelers.

Marketing 4.0 and Internet Technologies in the Tourism Industry Context

INTRODUCTION

The development of the Internet and Information and Communication Technologies (ICTs) have been an incredible change for Marketing studies and its classical main activities, price, product, promotion, and distribution. At present, new trends such as collaborative economy and Marketing of social CRM (Customer Relationships Management) content are emerging, affecting Marketing practices around the world (Kotler, Kartajaya and Setiawan, 2017). In this sense, the four “Ps” have been redefined by the four “Cs” (co-creation, currency, community activation, and conversation) (Kotler et al., 2017). These technologies have allowed promoting the development of co-creation activities, with the aim of creating long-term and trust relationships with end users.

Particularly, the technological revolution and value co-creation process have notably affected one of the main economic sectors of the world, such as tourism (Grissemann and Stokburger-Sauer, 2012). Highlights new models of more sustainable, personalized and efficient travel. Virtual reality tools, personalized hotel rooms, voice-activated devices, chatbots or facial recognition technology have facilitated and improved the relationship that, up to the present, companies, destinations, and consumers maintained (Hosteltur, 2019).

Certainly, the relationship between tourism and co-creation is a matter of special interest in the literature (Grissemann and Stokburger-Sauer, 2012; Binkhorst and Den Dekker, 2009; Riera et al., 2015; Prebense, Vittersø and Dahl, 2013; Lee, 2012; Cabiddu, Lui and Piccoli, 2013; Rihova et al., 2015; Suntikul and Jachna, 2016). Cutting-edge tourist companies are carrying out co-creation processes with their consumers. However, and despite its relevance in the innovation process, empirical evidence in research on co-creation in tourism is scarce. Also, there is not enough research on co-creation in tourism (Hoyer et al., 2010; Grisseman and Stokburger-Sauer, 2012; Lee; 2012; Rihova et al., 2015).

In this context, the main objective of this chapter is to study the co-creation process in the tourism sector. First, the evolution of Marketing is analyzed. Second, the value co-creation process strategy 4.0 is examined in the tourism sector. Finally, this study proposes some conclusions, limitations and further research.

DOI: 10.4018/978-1-7998-3473-1.ch115

BACKGROUND

In the past half century, Marketing has been through some different stages until reaching the most current era of Marketing, Marketing 4.0. As Erragcha and Romdhane (2014, p.137) posit “*Marketing is a discipline in constant change*”.

The first focus of Marketing is Marketing 1.0 and appeared after the Industrial Revolution due to the development of production (Kotler, 2012). It is a commercial approach to unidirectional management using traditional media (radio, press, television). In this era, the consumer is a passive user and the product is the focal point for the company (Erragcha and Romdhane, 2014). With reference to the tourism sector, a clear example of Marketing 1.0 is tourist brochures, which inspire consumers to choose the destination through photographs of monuments, places of interest and hotels.

Contrary to Marketing 1.0 only focused on the product, Marketing 2.0 places the customer in the middle of its vision (Kotler, Kartajaya and Setiawan, 2010). This is the result of the development of information technology and the Internet (Kotler et al., 2010). This is a new challenge faced by companies that must take advantage of social networks to reach customers directly and individually. In this new era, customers are well informed, can easily compare offers of similar products and choose between a set of functional and alternative features. In fact, each consumer has different preferences, so companies must segment and develop a superior product for a target audience (Kotler et al., 2010). Although companies begin to “touch” the heart and mind of consumers, even in Marketing 2.0, consumers are passive Marketing objects (Kotler et al., 2010).

The idea of Marketing 3.0 was conceptualized in 2005 by a group of consultants from MarkPlus, a Marketing services company led by Hemawan Kartajaya. After two years of collaboration with Philip Kotler, they launched the draft of the manuscript. In this new era of Marketing, companies stop focusing on the consumer and move to focus on the human being. It is the age driven by values. Instead of treating people as consumers, they are treated as human beings, with mind, heart, and spirit (Kotler et al., 2010). In this sense, consumers are concerned about sustainability and the environment and seek solutions to their concerns about globalization and economic justification. This Marketing is focused on the consumer, but the companies aim to contribute to the development of a better world and propose solutions to society’s problems (Kotler et al., 2010). As these authors point out, it is the era of participation and collaborative Marketing, globalization and cultural Marketing, the creative society and the Marketing of the human spirit. In Marketing 3.0, the co-creation concept was born. This concept was coined by Prahalad and Ramaswamy (2004) as a new approach to innovation. The consumer is demanding and informed, has more power with respect to the company and can participate in the development of certain processes with the company. However, companies must develop new strategies to achieve the active and total participation of consumers as well as their emotional commitment (Zarco et al., 2019). In this sense, the key can reside in Marketing 4.0.

Based on these notions, and as a result of the evolution of Marketing 3.0, a new era of Marketing was born, Marketing 4.0, the evolution of Marketing 3.0 when it is used intensively with technology (Zarco et al., 2019). Marketing 4.0 happens as a result of complex changes caused by the increase in global competition, better informed and more demanding customers and the rise of new technologies and innovations (Vassileva, 2017). This new approach is part of the digital age and combines online and offline interaction between companies and consumers (Kotler et al., 2017). The barrage of new technologies such as the mobile Internet, the automation of knowledge management, the Internet of Things (IOTs), cloud technology, robotic advances or 3D printing has helped to develop multiple new sectors of the economy. Above all, the mobile phone has brought peer-to-peer connectivity and more consumer power. At the moment, they are smarter and better informed than in the past (Kotler et al., 2017).

Marketing 4.0 focuses on “*social relationships*”. Currently, consumers rely on the opinions of other users and can make consumer decisions at any time and from anywhere. When they are interested in things they see on television, they turn to their mobile phone in search of opinions from other consumers. When they decide to buy something in the physical store, they look for the price and quality on the Internet. However, they also love to experience things physically and value “*engagement*” when interacting with brands (Kotler et al., 2017). Marketing 4.0 is also based on connectivity. As Kotler et al. (2017) point out, connectivity may be the biggest “*game changer*” in the history of Marketing, by reducing the costs of interaction between companies, workers, partners, customers and other agents of interest (Kotler et al., 2017). Digitization has transformed the decision-making process of the consumer. Therefore, consumers seek information, evaluate products and services, interact with the organization and make purchases (Vassileva, 2017). This decision-making process has been renamed “*the journey of the digital decision of the consumer*” (17). Marketing 4.0 is also be called *Big Data Marketing* by Zarco et al. (2019) and can help Marketing to achieve the company’s objectives. Also, it facilitates the understanding of consumer behavior, and as a result, allows designing Marketing actions that allow the customer’s shopping experience to be more personalized.

Although there has been much speculation, academic journals have published little about Marketing 4.0 (Zarco et al., 2019). For example, Zarco et al. (2019) analyze in depth various concepts of this new era of Marketing, examining how the use of large amounts of data can improve the relationship between the consumer and the brand. Vassileva (2017) analyze the main challenges and opportunities that companies face due to the new digital revolution represented by Marketing 4.0. Similarly, Jara, Parra y Skarmeta (2012) study the different elements of Marketing 4.0 and its evolution from Marketing 3.0; and Świeczak (2017) examines the main challenges generated from innovation and technology. For that, they suggest the conceptual framework D_3I_2C (Design-Direct-Development-Interventions-Innovation-Capacities) that combines the actions of Marketing and digital transformation. According to these authors, Marketing 4.0 is necessary because, nowadays, customers not only demand products that satisfy their needs but also products and services that fulfill their desires or alleviate their anxieties. They are looking for products that allow them to express their creativity and find in them the values defined by Marketing 3.0. In this sense, customers want to be part of the product, contributing and interacting with the company in any stage of its value process. In addition, they want to share their experiences and verify if the product really meets or exceeds the expectations (Łukowski, 2017).

Value Co-Creation in Marketing 4.0

Another of the fundamental premises of Marketing 4.0 is to consider that the structure of power has changed. According to Kotler et al. (2017), this drastic change has been promoted by the development and evolution of the Internet. The set of communication networks has brought connectivity and transparency so that companies have gone from having a vertical structure to a horizontal structure. Now it is the market that provides the ideas and the companies who marketed it (Kotler et al., 2017).

Connectivity has transformed the knowledge of consumers. Above all, social media platforms such as Twitter, Instagram, and Facebook allow customers to show and share their experience and, in turn, inspire other users to enjoy a similar experience (Kotler et al., 2017). Thanks to the integration of technology in Marketing, consumers look for products to which they contribute creatively and want to be part of the product, that is, they want to interact with the product and share their experiences using information technologies (Zarco et al., 2019).

In this new generation, customers not only look for products to satisfy their basic needs, desires or concerns. They also want to express their creativity and the values defined in Marketing 3.0 (Vassileva, 2017). As Kotler et al. (2017) argue, users were influenced by the Marketing campaigns of companies in the past. At present, they trust more in the factor f (friends, relatives, followers and followers) than in experts' opinions. Increasingly, users take into account the comments of other users and the joint design of the brand image or the brand company, which is sometimes very different from the companies that try to project. In this way, the Internet and social media are responsible for the change that has happened in the company-consumer relationship, by providing the platform and online tools. At present, users are no longer passive objects but have become co-creators of value (Kambil, Frisessen y Sundaram, 1999, Prahalad and Ramaswamy, 2004, Binkhorst and Den Dekker, 2009; Rihova et al., 2018, Dolan, Seo and Kemper, 2019). Due to technology, consumers have acquired a new behavior, so they want to know if the goods and services are produced efficiently by the company and if it is sustainable in environmental, economic and social terms (Zarco et al., 2019).

The term co-creation was initially proposed at the end of the 1990s by Kambil et al. (1999) in their article "*Reinventing Value Propositions*". In this study, these authors identified four different functions that customers could perform in their relationship with suppliers, noting as one of these functions as co-creator. This term was referred to how customers cooperate with their suppliers to produce joint value. A few years later, the concept was coined by Prahalad and Ramaswamy in their study "*Co-Opting Customer Competence*" to describe the emerging relationship between customers and companies (Ramaswamy and Gouillart, 2010). In 2004, these same authors developed the concept with the publication of the book "*The Future of Competition*". In this book, they argue that the value is co-created at the point of interaction between the company and its customers. Also, it is created from the experience of such interaction and not derived from a physical product. Since then, the concept of co-creation has been widely studied in the context of Marketing (Zarco et al., 2019) in several areas of research and it has been used in different literature approaches. The concept has become a topic every time more complex (Galvagno and Dalli, 2014). As Ramaswamy (2011) points out, co-creation of value is a widely used term that encompasses everything that denotes the creation of mutual value by several actors. Undoubtedly, one of the most current definitions is provided by Zarco et al. (2019, p.6). These authors consider co-creation a joint creation process in which consumers participate in different value creation activities through which products and services are developed.

Value Co-Creation in Tourism

In particular, social media has completely changed the way in which information related to tourism is generated and distributed (Dolan et al., 2019). The tourism industry is characterized by high contact services, and tourists play an important role in the co-creation of tourist services (Grisseemann and Stokburger-Sauer, 2012). Co-creation in the tourism sector is understood as "*the contribution of inputs made by the customer in the planning process of his trip*" (Grisseemann and Stokburger-Sauer, 2012, p.1484). In this process, clients are considered employees of the company (prosumers) and are partially responsible for their result (Xie et al., 2008). Therefore, they have the freedom to co-create their own experiences (Binkhorst, 2006; Ramaswamy and Gouillart, 2008).

The application of value co-creation in tourism is a matter of special interest in the literature due to the unique characteristics of tourism products and services. Being intangible experiences cannot be measured or evaluated before consumption (Lee, 2012). Therefore, the suggestions and ideas of tourists and travelers are especially important and basic because they will experience if the innovation is effective

or not (Binkhorst and Den Dekker, 2009). Thus, through the process of co-creation, tourism planners and managers have the opportunity to connect with customers in more touch points and influence their level of satisfaction, loyalty, and word-of-mouth (Oliveira and Panyik, 2015).

Currently, and from the academic point of view, publications related to co-creation are increasing in the tourism sector (Binkhorst and Den Dekker, 2009; Grisseemann and Stokburger-Sauer, 2012; Neuhofer, Buhalis y Ladkin, 2012; Rihova et al., 2015; Mathis et al., 2016; Lin, Chen and Filieri, 2017; Shen, Li and Zhang, 2018). As regards work, there are many tourist companies that have developed co-creation activities with their consumers. At present, tourists are more technological and innovative users, looking to enjoy their hobbies and their stay at the destination is shorter. In general, they are looking for an authentic experience (Hosteltur, 2017). On the other hand, the consumer's relationship with tourism products has changed. The company not only informs the tourist, but also company has two-way communication with him. Thus, the process of creating tourist products has also been changed. In this sense, tourism companies not only create and innovate products and services but also co-create with customers (Hosteltur, 2017). Tourists can plan their own trip surfing the web and sharing their own experiences and other travelers' experiences through social networks. As a result of this search on the web, the image of a tourist destination is created and disseminated through these communication tools.

Because of its importance in the planning of a trip, social networks have become a key platform for companies to develop activities jointly with tourists. Through these information and communication tools, they must respond to the comments and ideas provided by users, solving possible problems and accompanying the traveler in the different stages of their trip. In this way, the collaboration and interaction between both parties will improve the travel experience for the user. As a result, this positive travel experience will be projected on social networks creating a favorable image of the destination in the different online platforms.

Then, and based on this literature review, this research work analyzes five cases of companies in the tourism industry that have successfully developed co-creation activities with consumers, using different types of social media with as an online platform.

KLM Royal Dutch Airlines

The Dutch airline KLM has launched an innovation project in collaboration with its customers and through social networks. Using these platforms, travelers can choose the person they want to sit with during the journey, simply by accessing the public profile of these people on LinkedIn and Facebook. Through the “*Meet and Seat*” program, many users are willing to share their profile on these social networks in exchange for knowing someone with common interests and travel to the same destination (ElPaís, 2012). After booking the flight ticket and selecting the personal information that you want to share, the passenger can visualize a map with all the seats of the plane and see where others are seated. Previously, they have also shared their social profile. In this way, the user can reserve the next seat that seems most interesting and then, the selected person will receive a message with all the details (ElPaís, 2012). As the director of the company, Erik Varwijk, points out “*the objective of this service is to connect passengers with similar interests and have a more inspiring journey*” (www.klm.com). For example, users can meet for coffee before the flight, select adjoining seats and decide to share a taxi when landing. The program allows users to share the information they want publicly and make the reservation of the seat from 90 days to 48 hours before departure. This program is available for free only for flights between Amsterdam and San Francisco, New York, and São Paulo. On its website (www.klm.com) there

is a video tutorial showing a map with the seats of the plane. Therefore, consumers can reserve a seat next to a person with similar interests.

In the previous year, KLM launched a contest on its Facebook page to decorate one of its Boeing 777-200 aircraft. Through the Tile & Inspire campaign, the company invited users to create a Delft-style tile with their photo and include a phrase. Four thousand photographs were chosen to decorate the exterior of the plane through tiles in white and blue colors (diariodelviajero.com).

Seville (Spain)

In 2015, through a tourist promotion campaign called “*There is another Seville ... full of experiences*”, the Spanish tourist destination invited users of social networks to send videos of their own tourism experiences in Seville. The objective was to promote the city through original and personal photographs of travelers and users who would make known different aspects and attributes of the Andalusian province. The project was divided into eight categories (Lodgings with charm, Bulls and Horses, Gastronomy, Heritage, SVQ Province Tourism, Festivities, Industrial Tourism, Nature and Active Tourism). As a result of the project, different images were selected to produce a video of tourist promotion of the province of Seville (Prodetur, 2014).

This project, promoted by the Tourism Portal of the Province of Seville, had enormous potential in terms of visual material. The images shared reflected personal experiences of the tourists themselves. The videos and photographs were promoted by individual people, like the videos produced by Marketing agencies. The prize for the most voted video was a stay of two nights and three days in the city that included different experiences, such as a scenic flight through the province, a cruise on the Guadalquivir, visit livestock, two gastronomic experiences and a stay in a hotel (Prodetur, 2014).

Barceló Emperatriz Hotel (Madrid, Spain)

Some companies have gone a step further and have decided to involve their users and followers of social networks directly in the creation of a product or service through a co-creation process. This is the case of the Hotel Emperatriz in Madrid (Spain), which has been completely renovated thanks to an innovative process of co-creating value with its customers. The hotel, belonging to the Barceló travel chain, launched a proposal in June 2015 through social networks and on its website through a platform where the clients themselves contributed their ideas and suggestions. Subsequently, the best ideas were chosen by a court. Once the proposals were approved, they were published on the social networks of the Barceló Emperatriz Hotel and their followers could continue to add new ideas in the furniture and other hotel services (Barra de Ideas, 2016).

In total, more than 1,500 proposals were received. Among these measures have included among other changes in the reception area, in the decoration, greater variety in the breakfast, greater provision of chargers and HDMI and USB ports in each room, a healthy mini bar with the preferred products by Guests and room service 24 hours. Thanks to this co-creation process, the Emperatriz Hotel has gone from being a four-star hotel to becoming a five-star hotel, building a special and different hotel and surprising the most demanding travelers. According to the director of Marketing of Barceló Hotels & Resorts, “*the objective of this co-creation project was to create a different hotel, with unique experiences and with proposals by the future customers*”. This project has allowed the company to actively listen to the customer’s needs, giving them the opportunity to participate in a project with ideas not found in other similar hotels (Expreso, 2015).

Marriot International Hotels

With 500 hotels in 60 countries worldwide, Marriot International launched a successful program called Travel Brilliantly, taking advantage of the launch of the latest Go Pro camera model, Hero 4 model. Due to this launch, the Marriott hotel chain saw an incredible opportunity for its customers to share their tourist experience in her hotel facilities. To do this, the hotel company invited its customers to use the latest Go Pro camera model for free. In return, the company requested they share their photographs and videos through social networks with the hashtags #GoPro #TravelBrilliantly and #Viajegenial, with the possibility of showing their video or photographs on the Marriot website. The objective of the company was to raise the tourist experience of its guests from the Caribbean and Latin America to the highest level. In this way, tourists can share their travel stories in a fun way and directly share their experience with friends, acquaintances, and family. Thus, travelers themselves are used as a source of inspiration and a key motivation for other tourists to stay at one of the Marriot hotels, and like them, enjoy the Go Pro camera during their stay. In addition, customers can get prizes such as Marriott Rewards points, holiday stays, and GoPro cameras. On the other hand, the hotel company can differentiate itself from similar competitors by providing its customers with the enjoyment of incredible and unique experiences.

Heineken

In 2010, Heineken proposed travelers from John F. Kennedy Airport in New York to change their travel plans and venture to visit a known destination. If they want to live a new adventure, they had to participate in Roulette Departure Roulette, a roulette created by the Heineken company to travel to the destination indicated by the game. Thanks to this proposal, the online series Dropped was launched, showing in 12 chapters the adventures of four men who were sent to different destinations in the world with only their clothes and a ticket back to their place of origin (YoungMarketing, 2013). In addition, the followers of the series could send their own experiences to the platform. Heineken's initiative wants to inspire beer consumers to be travelers, not only tourists.

Simultaneously and due to its success, the company developed a strategy for selling special packs of beer. Inside these packs, there were codes for customers to participate in an online game based on skills for survival with the option to win a trip adventure, such as space training. In this way, Heineken consolidates itself as an innovative company that is committed to new Marketing trends, effectively building strong communication relationships with its customers (YoungMarketing, 2013).

CONCLUSION

This study has conceptually pursued three objectives: (1) to examine evolution from Marketing 1.0 to Marketing 4.0; (2) to analyze the concept of value co-creation process and its application in the tourism sector; and (3) to propose several success stories of companies that have involved their consumers in the production process.

Therefore, and based on the review of tourism literature, this work has contributed to a greater knowledge of the meaning, analysis, and application of co-creation in tourism. As suggested by different authors, the value co-creation process is an area unattended in tourism and there are still many unsolved questions in this regard (Grissemann y Stokburger-Sauer, 2012; Lin et al., 2017; Rihova et al., 2018). Above all, research on co-creation and technology in tourism is scarce (Von Solms and Von Solms, 2016).

Undoubtedly, the use of co-creation activities is particularly interested in the tourism industry due to the intangibility of the services. Being intangible, consumers can not experience tourist products and services previously. So, the ideas, comments, suggestions, photographs, and videos of other tourists and travelers become a very reliable source of information when choosing a destination. As Kotler et al. (2017) point out, most consumers are influenced today by the factor f (friends, family, followers, and fans).

FUTURE RESEARCH DIRECTIONS

Despite the relevant contributions to the academic literature, this study has limitations that must be considered as an opportunity for future research. In the first place, this work is a theoretical investigation so that, future research should empirically analyze value co-creation in the tourism sector. Secondly, it would be interesting to examine the reasons that lead tourists and travelers to share their tourism experience through co-creation. Knowing the motivations of the users will enable companies to develop effective, pleasant and entertaining co-creation strategies for its consumers. These activities must generate significant interest in the consumer and, consequently, get ideas and valuable suggestions for the innovation company process. Third, this work has focused on analyzing several success stories of companies in the tourism industry that have to carry out co-creation initiatives with their consumers. However, it would be interesting to examine empirically a specific co-creation project and see what its impact on consumer satisfaction and loyalty, and the other hand, its impact on different result company variables, such as its brand image.

KEY TERMS AND DEFINITIONS

Big Data Marketing: Set of tools and technological techniques based on the process of large amounts of information in real time, that allow a company to know consumer behaviors and attitudes in the purchase process.

Internet Technologies: Application of technologies and Internet-based communication and information tools to get, store and send data in the business context.

Marketing 1.0: The first focus of Marketing which consumer is considered as a passive user and the product is the focal point for the company.

Marketing 2.0: The second era of Marketing based on social networking sites which consumer is the focal point for the company.

Marketing 3.0: It's the era of Marketing that considers consumers as people with heart, mind and spirit. Marketing 3.0 appears due to factors such as globalization, creativity and the technology development.

Marketing 4.0: New area of Marketing where technology and digitalization have leveraged consumers to be part of companies, participating in the innovation and development of products and services through value co-creation activities.

Value Co-Creation: Collaboration and creative process between the company, consumers and other interest groups based on the interaction, and through which companies develop new products and services.

Destination@–Branding and Re–Branding of Ten European Capitals

Elena Bocci

Sapienza University of Rome, Italy

Annamaria Silvana de Rosa

Sapienza University of Rome, Italy

Laura Dryjanska

Rosemead School of Psychology, Biola University, USA

INTRODUCTION

Starting from a broad research programme on *Place-identity and Social Representations of European Capitals in first visitors of six different nationalities* begun by de Rosa in the 1990s (de Rosa, 1995; 2013b) - later developed along multiple interrelated research lines based on *field studies* and *media studies*, inspired by the *modelling approach* (de Rosa, 2013a; 2013c, 2014) - this contribution represents an integrative work concerning a study on the *Destination@-branding* (Morrison & Anderson, 2002) of ten European Capitals through communication via their institutional stems and commercial logos.

The brands of Rome, London, Paris, Helsinki, Vienna, Warsaw, Berlin, Madrid, Brussels and Lisbon are the symbolic tools and cultural artefacts created in different historical periods in order to contribute to the “*distinctiveness*” of the different cities.

Therefore, the first aim is to compare the iconic structural elements of the brands (ancient and modern stems and logos) of ten European capitals, which play a determinant role in the narration of urban history.

This research also compares the social representations evoked by brands (stems and logos) of the ten European Capitals among potential first-visitors.

Moreover, by considering that branding is an evolutionary process (re-branding), this contribution analyses the recent transformations of some commercial brands from a longitudinal perspective.

Finally, this contribution integrates the results of the analysis of the main graphic elements of branding in the framework of the more complex research programme (de Rosa, Bocci, Dryjanska, 2019), suggesting a preliminary overview of the Destination@-Branding focused on the iconic social representations.

THEORETICAL BACKGROUND

Destination branding constitutes a way to communicate a destination’s unique identity by differentiating a destination from its competitors (Morrison & Anderson, 2002; Mitoula, 2019).

According to different authors (Cai, 2002; Florek, Insch and Gnoth, 2006; Nandan, 2005), brand identity and brand image are critical ingredients for a successful destination branding, including two different perspectives:

DOI: 10.4018/978-1-7998-3473-1.ch116

- the “marketers” who desire to create the brand identity;
- the “targets” who perceive the brand image (Kapferer, 1997; Florek, Insch and Gnoth, 2006; Qu, Kim & Im, 2011).

In particular:

- Kapferer (1997) and Konecnik & Go (2008) state that before knowing how a place “is” perceived by tourists, it is important to establish how a place “should be” perceived by its target audience; Aaker & Joachimsthaler (2000:68) define brand identity as: “a unique set of brand associations that the brand strategist aspires to create or maintain. These associations represent what the brand stands for and imply a promise to customers from organization members”; while
- following Keller (1998:93) and Cai (2002:723), brand image can be defined as: “perceptions about a place as reflected by the brand associations held in tourist memory; or as a combination of cognitive and affective evaluations stored in the consumers’ minds” (Baloglu & McCleary, 1999; Pike, 2009).

The relationship between destination brand identity and brand image can be considered as circular and dialogic:

- brand image plays a significant role in building brand identity (Cai, 2002);
- brand image is the reflection of brand identity (Qu, Kim & Im, 2011:467); “the reaction to this message in the minds of recipients” (Florek, Insch & Gnoth, 2006:279).

The distinctive and unique image deriving from the brand image differentiates the destination from the competitors and can be used by the marketers for destination branding. In fact, as stated by Cai (2002:722): “Image formation is not branding, albeit the former constitutes the core of the latter. Image building is one step closer, but there still remains a critical missing link: the brand identity”.

The model of destination branding proposed by Cai (2002) is organized around three central elements: brand identity, brand image and brand element mix featured in this contribution. The process starts by choosing one or more brand elements -identifying the destination- and goes on with the formation of “brand associations” (attributes, affective and attitudes components of an image -see also Gartner, 1993; Keller, 1998) driven by brand identity.

Moving beyond the molecular studies interested in identifying the cognitive and evaluative factors in perception, purely focused on the processes of categorization, encoding, storage and retrieval of information in memory, this article captures the multi-dimensionality of the Social Representations Theory (Moscovici, 1961/1976; Jodelet, 1989; de Rosa, 2013a; 2019; de Rosa, Dryjanska & Bocci, 2017; de Rosa, Bocci & Dryjanska, 2018).

MAIN FOCUS: DESTINATION@-BRANDING AND RE-BRANDING OF TEN EUROPEAN CAPITALS

From the recent review of the City Branding literature conducted by Kasapi & Ceia (2017:139): “it can be concluded that the field of studies of destination branding in general and that of city branding specifically are still in their infancy suggesting that more studies can be conducted in these fields”.

This chapter welcomes the above suggestion and proposes a re-interpretation of “destination branding” in terms of “destination@-branding”, considering the aforementioned ten European Capitals, not only as objects of perception, but, in a more comprehensive way, as objects of representation (Vanolo, 2010) in light of the Social Representations Theory.

Starting from the awareness that the competition for distinctiveness is very high and the cities are continuously looking for new ways to improve their identity with the purpose of attracting visitors, this chapter highlights the power of logos in Tourism Destination Branding (Blain, Levy & Ritchie, 2005) as iconic component of Social Representations. However, if logos have to be defined and re-defined because their aim is “to sell the city product” -starting from the assumption that places can be branded just like products to maximize their attractiveness and their enjoyment by visitors (Ashworth, 1994; Anholt, 2003, 2010; Freire 2005)- in light of the social representations theory it is important to take in account that: to transform the symbol means to change directly the entity that it represents (Bocci, de Rosa & Dryjanska, 2017).

Modelling Approach Research Design

Given the relevance assigned to the iconic-imaginary dimension of Social Representations by the “modelling approach”, the brands have been studied by using an appropriate research design as described in Table 1. The *modelling approach*, developed by de Rosa (2013a, 2014) is a paradigmatic option specific to the research field inspired by the Social Representations Theory. It is aimed to grasp its core value as a unifying meta-theory of the social sciences, by operationalizing the investigation about any object of this supra-disciplinary field in multi-methodological research designs. These require to be fully justified and adequately complex depending on the multi-theoretical perspective adopted and the variety of constructs selected (representations, identity, social memory, emotions, etc.), the diverse techniques of

Table 1. The main features of the research design

Objective	Hypothesis and main questions	Methodology
The research compares the social representations evoked by brands of the ten European Capitals among potential first-visitors. The first aim is to compare these iconic elements (ancient and modern) of ten European capitals (Rome, London, Paris, Helsinki, Vienna, Warsaw, Berlin, Madrid, Brussels and Lisbon), which play a determinant role in the narration of urban history. By considering that the branding is an evolutive process (re-branding) this contribution also analyses the recent transformations of some commercial brands from a longitudinal perspective. Finally, this contribution integrates the results of the analysis of the main graphic elements of the branding, in the framework of the more complex research programme, suggesting a preliminary overview of the Destination@-Branding, to be further integrated.	It is expected to identify discrepancies and/or contrasts of meaning between institutional stems and commercial logos – both in terms of structure of the elements that characterize these brands, and concerning their social representations – since, even though both are aimed at distinctiveness and recognition: 1. stems have historic roots, which often date back to the origins of the city; 2. logos were created in modern times, for well defined marketing purposes. In order to test the hypothesis, it is necessary to answer the following questions: 1. Which are the structural elements of the stems and logos? 2. Which are the main differences between the social representations evoked by stems and logos? (strengths and weaknesses; attitudes etc.) 3. Concerning commercial logos, is it possible to improve them? Finally, in light of the wider research programme, how the symbolic power of institutional stems and commercial logos is articulated in the complex scenario of the Destination@-Branding?	The social representations of the brands are identified through the “associative network” (de Rosa, 2002) using as iconic stimuli both the stems and the logos of each of the ten Capitals. Moreover, a grid has been created ad hoc to identify the distinctive elements of the brands. For a description of the methodology related to Institutional tourist websites and forum discussion on the TripAdvisor portal see: de Rosa, Bocci, & Dryjanska, 2019.

data collection (structured and projective, textual and figurative, verbal or behavioural, etc.), the choice of the data analysis strategies and the expected results.

Research Focus

In this contribution the following brands (institutional stems and commercial logos) have been considered (see figure 1):

Figure 1.

Research Instruments and Data Analysis Strategies

Structural and projective techniques have been created or developed, considering as iconic stimuli a coat of arms and a logo for each Capital -as shown in Figure 1, above city names-.

- a) The grid is a structured tool, in format of a table, realized ad hoc for this research line and aimed to detect the presence/absence of the following distinctive components of the brands:
 - Name of the capital and texts in national languages;

- Slogan;
- Acronyms and texts in Latin language;
- Royal elements;
- Elements of military origin;
- Religious or symbolic/mythological elements;
- Natural elements;
- Abstract graphic elements.

The grid has been applied to all stems and logos in order to identify the main structural elements of the different brands.

b) The “associative network” (de Rosa, 2002)

is a tool of a projective nature; therefore it is less subject to the phenomenon of social desirability, if compared to structured tools like for example a questionnaire. It enables respondents to specify the structure, content and polarity of a semantic field by themselves.

The tool requires first to associate words with stimuli (a stem and a logo for each city) and then to establish connections and branching patterns between the elicited words that are written around the brand.

The associative network requires people to attribute a particular polarity to each word (positive, negative or neutral) to describe its connotations. This allows to detect the evaluative component of the representations. A polarity index calculates the positive, negative, or neutral connotations of the free associations evoked by each of the iconic stimulus used in this study.

This index, which varies from +1 to -1 is calculated using the following formula:

Polarity Index (P) = (n° of positive words – n° of negative words)/total n° of associated words.

A second “neutrality” control index, which also varies between -1 and +1, is also calculated.

Neutrality Index (N) = (n° of neutral words - (n° of positive words + n° of negative words))/total n° of associated words.

Using the software SPAD (Lebart, Morineau & Be ue, 1989) applied to the associative network, it is possible to reconstruct the structure and content of the representational fields associated with the iconic stimuli (procedures *Talex* -contingency tables- and *Corbit* -analysis of latent dimensions, including as active variables indexes and words evoked-).

For each of the iconic stimuli the first five factors were extracted, whose cumulative percentage of variance explained more than 80% of the total.

Among the indicators useful in the interpretation of the results, the following are taken into account:

- the factorial coordinates of each word on the first 5 factors which establish their position in the axes, in terms of distance from the origin and positioning on the positive or negative side;
- the absolute contribution, which constitutes the part of the total inertia of the factor explained by each variable (Ercolani, Areni & Mannetti, 1990);
- the relative contribution, or cosine squared, which assesses the contribution the factor provides to the explanation of the variability of each modality.

The analysis makes it possible to identify hidden dimensions (factors) that are subtended to the data and summarize the relations between original variables.

The aim is that of rendering simpler the interpretation of the whole range of information through a synthesis, so that newly identified factors could represent a good approximation of the starting data-matrix. This chapter takes into account the factorial interpretation, leaving out further elaborations of geometric-structural nature.

The analysis was carried out on a group of 40 potential first-visitors, experts in training in “Marketing and Communication” (Master level) at the Faculty of Medicine and Psychology - Sapienza University of Rome. They have followed the Laboratory of Web Marketing, focusing the analysis of Social Representations of Historical Capital Cities.

The Main Structural Elements of the Different Brands

The analysis of the brands, made using the *ad hoc* designed grid, highlighted differences between stems and logos under scrutiny (see figure 2).

Figure 2 allows us to answer the following question:

Figure 2.

Question 1): Which are the structural elements of the stems and logos?

The stems origin from heraldry and evoke the prestige of the cities through rich combinations of different kinds of elements: royal, military, religious or symbolic/mythological and natural. In many cases, the history of the city contains elements of legends or religious beliefs, often recalling virtues of the Saints:

- the “armed mermaid” recalls a mythological figure prepared to protect the city of Warsaw and its inhabitants;
- the “dragons” refer to Saint George’s victory over one of them depicted in the stem of London;
- the “crows” in the stem of Lisbon lift up in the air the body of Saint Vincent, then recovered by his followers;
- the “burgundy color” of Rome recalls the legend of Ancile, one of twelve sacred shields kept in the Temple of Mars, which fell from heaven during the reign of Numa Pompilius to protect the city;
- the “Archangel Michael” pierces the black devil in the stem of Brussels.

These elements present in the stems narrate the history since the cities' foundation. On the commercial logos complex figures disappear completely, leaving space to modern elements: essential lines, abstract signs and circles innovating the brand and referring to socio-recreational, emotional, architectural and design aspects.

The Iconic Social Representations Through the Brands

The figure helps us to answer the question (see figure 3):

Question 2): Which are the main differences between the social representations evoked by stems and logos? (Strengths, weaknesses, attitudes)

The figure 3 compares the average polarity indexes calculated from the positive, negative and neutral assessments attributed by research participants to the associations evoked by the stems and logos of the ten European Capitals.

Figure 3.

First, the cases where the average polarity index of the representational field evoked by institutional stems is lower shall be examined. *Which social representations are evoked by these stems?*

In both cases the overwhelmingly important topic is “war”.

Concerning the city of **Berlin** (average index of polarity institutional stem 0.040), next to the functional aspects of a city considered as “organized” (first factor, positive semi-axis, a.c.3.6 r.c.0.49) appears the historic-artistic-cultural dimension with terms such as “wall” (a.c.7.9 r.c.0.78) and “museums” (a.c.3.1 r.c.0.29) on the negative semi-axis of the first factor; “Brandenburg Gate” (a.c.6.2 r.c.0.43) and “culture” (a.c.5.2 r.c.0.40) on the positive semi-axis of the second factor; the tight relationship of art/culture with the darkest period of recent history tends to be associated with a negative polarity index on the two factors (negative semi-axis of the first factor a.c.11.8 r.c.0.26; positive semi-axis of the second factor a.c.11.9 r.c.0.16).

The binominal art/culture and the history of the XXth century can be seen even clearer in the social representations of stems, as demonstrated in the first two factors: the first factor -negative semi-axis- includes such terms as: “nazism” (a.c.17.8 r.c.0.89), “East Berlin” (a.c.11.1 r.c.0.68), “war” (a.c.10.3 r.c.0.88) and “wall” (a.c.5.1 r.c.0.37) and the second factor – negative semi-axis- includes such terms as: “wall” (a.c.8.7 r.c.0.50) and “violence” (a.c.4.1 r.c.0.30). In both factors active variables elicited coincide with a negative polarity index (negative semi-axis of the first factor a.c.14.2 r.c.0.33; negative semi-axis of the second factor a.c.11.2 r.c.0.51).

The second factor in particular shows a split in the attitudinal component of social representations; while the negative polarity goes with the historical events of the last century, the positive polarity corresponds to recent cultural events (“Cinema Festival” a.c.10.2 r.c.0.60) and to ancient history of the city (“ancient” a.c.4.2 r.c.0.37).

References to the XXth century for the city of Berlin are in continuity with the city of Warsaw (average index of polarity institutional stem 0.1393) whose brands are full of events related to World War II. In reference to the commercial logo, the word “Auschwitz” occurs on the second factor of the positive semi-axis (a.c.15.2 r.c.0.53) next to “cold” (a.c.26.6 r.c.0.78) and “sad” (a.c.11.4 r.c.0.86) associated with a negative polarity index (a.c.70.6 r.c.0.96); on the positive semi-axis of the fourth factor (a.c.10.1 r.c.0.14), as well as on the negative semi-axis of the fifth factor (a.c.21.6 r.c.0.22).

The history of the XXth century also shows an impact on the social representations evoked by the stems. The first factor in particular demonstrates a rift in the attitudinal component of social representations:

- on the positive semi-axis the positive polarity (a.c.26.8 r.c.0.79) corresponds to general aspects such as “history” (a.c.5.4 r.c.0.29) and nature-related themes (“river” a.c.7.1 r.c.0.60);
- on the negative semi-axis negative polarity (a.c.43.1 r.c.0.83) corresponds to the references to the “difficult” (a.c.7.5 r.c.0.65) period of the Second World War that caused suffering and victims, with terms like “blood” (a.c.14.4 r.c.0.68) and “war” (a.c.10.6 r.c.0.63).

The word “Auschwitz” appears on the positive semi-axis of the second factor (a.c.45.9 r.c.0.73), together with “Poland” (a.c.19.0 r.c.0.82) and “antique” (a.c.14.3 r.c.0.40), contaminating time and space, and on the positive semi-axis of the third factor (a.c.11.5 r.c.0.14) together with “war” (a.c.6.4 r.c.0.23).

Next, the city of **Lisbon** (average index of polarity institutional stem 0.5135) is examined; the only case where the stem has a more positive evaluation than the logo.

What are the strengths of the institutional stem and what are the weaknesses of the commercial logo?

The richness of details -that take us back in time to the colonialism- and the predominance of yellow are the strengths of the stem; while, having taken over the central part of the emblem, using only the black colour and clean lines leads to more negative evaluation of the commercial logo.

In spite of common elements:

- for the stem the positive social representations coincide with the references to “colonialism” presented on different factors: negative semi-axis of the third factor with keywords such as “wealth” (a.c.6.5 r.c.0.32), “history” (a.c.6.1 r.c.0.66), “power” (a.c.5.4 r.c.0.43) and “sea” (a.c.3.1 r.c.0.24); positive semi-axis of the fourth factor with the keywords “Middle Ages” (a.c.6.3 r.c.0.19) and “boat” (a.c.7.3 r.c.0.37) and also on the negative semi-axis with “colonies” (a.c.9.1 r.c.0.39), “riches” (a.c.7.0 r.c.0.32), “trade” (a.c.6.0 r.c.0.37) and “discovery” (a.c.4.2 r.c.0.45); positive semi-axis of the fifth factor with the words “colonies” (a.c.11.7 r.c.0.34), “trade” (a.c.6.0 r.c.0.25), “discovery” (a.c.5.1 r.c.0.37), “boat” (a.c.4.8 r.c.0.16);
- for the commercial logo the negative polarity index corresponds to the positive semi-axis of the second factor (a.c.46.2 r.c.0.72) and to the negative semi-axis of the third factor (a.c.8.5 r.c.0.9) to the negative emotion “sadness” (respectively a.c.34.1 r.c.0.73 on the second factor and a.c.6.1 r.c.0.9 on the third factor), also associated with the “black” colour on the second factor (a.c.12.5 r.c.0.47).

The following section features the analysis of the cases where the positive polarity index of the commercial logos are higher:

Which social representations are evoked by these logos?

Social representations associated with the logo of **Brussels** (average index of polarity for commercial logo 0.6855), rich in metaphors, are centered on the topic of “multi-culturalism”. Sometimes interpreted as a “bar code” (first factor negative semi-axis a.c.54.1 r.c.0.91; second factor negative semi-axis a.c.8.2 r.c.0.6), the colors bring to mind the idea of a “game” (first factor negative semi-axis a.c.24.1 r.c.0.56), in other cases they are a synonym of the “rainbow” of races-cultures (third factor positive semi-axis a.c.5.5 r.c.0.43; fifth factor negative semi-axis a.c.5.5 r.c.0.20), an invitation to “open up” (third factor positive semi-axis a.c.8.0 r.c.0.42) and to “love” (a.c.5.2 r.c.0.19). Love appears both on the positive semi-axis of the third factor and fourth factor (a.c.4.5 r.c.0.13), here also together with “multicultural” (a.c.3.2 r.c.0.21).

The content associated with the institutional stem of Brussels appears very different from the one evoked by the commercial logo, concentrating on the historical/cultural and religious elements evoked by the legendary mythological figures.

After **Brussels**, also the commercial logos of **Madrid** and **Paris** are very positive.

For Madrid, the positivity seems related to “nightlife” that cuts across different factors, referring to socio-recreational city through more keywords: the “night life” appears on the negative semi-axis of the second factor (a.c.6.8 r.c.0.46), together with “inviting” (a.c.5.5 r.c.0.39) and on the positive semi-axis of the fifth factor (a.c.6.2 r.c.0.25), together with “happiness” (a.c.14.7 r.c.0.63), “sea” (a.c.13.7 r.c.0.59)

and “youth” (a.c.4.9 r.c.0.76); on the positive semi-axis of the third factor there is “*movida*” (a.c.3.3 r.c.0.20), together with the “sun” (a.c.4.9 r.c.0.66), “sea” (a.c.3.8 r.c.0.20) and “heat” (a.c.3.5 r.c.0.12).

Free associations related to the institutional stem of Madrid do not seem to refer to the characteristic “*movida*” (nightlife), concentrating on a descriptive/evaluative dimension of the elements represented.

Also for Paris, as in case of Madrid, the relational dimension is enhanced in the commercial logo from a more intimate perspective, which leaves room for romance, as in the third factor extracted. On the positive semi-axis it is possible to see in fact words like “charming” (a.c.16.4 r.c.0.65), “romantic” (a.c.8.7 r.c.0.63), “magic” (a.c.7.3 r.c.0.56), “evening” (a.c.4.7 r.c.0.29), “lights” (a.c.3.2 r.c.0.11); on the negative semi-axis of the same factor the dimension of values is expressed through such terms as “love” (a.c.13.0 r.c.0.72) and “Christmas” (a.c.4.8 r.c.0.28); “Christmas” (a.c.20.0 r.c.0.48), “fascinating” (a.c.9.7 r.c.0.16) and “romantic” (a.c.3.5 r.c.0.11), repeated on the positive semi-axis of the fifth factor.

The relational/value dimension is also detected in reference to the institutional stem; on the first, second, fourth and fifth factor the words “light” and “romantic” recur, repeated on the positive semi-axis of the second factor in correspondence with “love” (“lights” a.c.5.4 r.c.0.26; “romantic” a.c.5.4 r.c.0.26; “love” a.c.4.3 r.c.0.51).

Transformation of the Iconic Social Representations Through Re-branding

Question 3): Concerning commercial logos, is it possible to improve them?

By considering that branding is an evolutive process (re-branding) here we propose the recent transformations of some commercial brands in a longitudinal perspective. (See Figure 1, logos placed under the names of cities: Rome, Paris, Brussels, Helsinki, Lisbon, London, Vienna).

At a check for the three commercial logos that in Figure 3 showed the most positive attitude by the research participants (Brussels, Madrid and Paris) it is possible to observe:

- partial re-branding of Brussels with the elision of the string of colors sometimes eliciting a “bar code” in the participants;
- no re-branding in the case of Madrid;
- a very important re-branding in the case of Paris which, however, with the letter A of Paris, still refers to the Eiffel Tower, already emphasized in the logo object of our research.

Even Lisbon, whose commercial logo had registered the less positive attitudes -compared to other logos and the city’s institutional emblem-, provided a new brand.

Among the capitals with a lower polarity index for the commercial logo -Helsinki, Berlin and Warsaw- only the former made an important re-branding, while the other logos remained unchanged.

As reported by the official website of Helsinki, widely justifying the decision: “The reform of the City organization offered a good opportunity to unify the City’s brand identity. Now that the entire organization produces and uses materials based on a uniform identity, the City’s actions can draw more attention and be more efficient, as well as saving money. For citizens the reform means increasingly clear, easily understood and more resident-oriented marketing and communication about the City and its services. People working in Helsinki or visiting the city will perceive Helsinki more easily than before as a straightforward, appealing, modern, functional and enjoyable place. The uniform identity also helps Helsinki to differentiate itself from other cities and regions... The design of the brand identity was carried out by the brand design agency Werklig, which was selected through a competitive bidding process. The design work was assisted by several City experts. The adoption of the brand identity was decided

by the Mayor. The introduction of the new brand identity throughout the organization will take time. It is likely that many years will pass before the identity is fully established” (www.hel.fi).

After this study, also Rome has modified its commercial logo, the new one including a strong “relational” attachment and identification dimension (www.comune.roma.it).

However, on the occasion of the anniversary of the birth of Rome (April 21st 2016) Italian newspapers have titled that the Special Commissioner of Rome Mr. Tronca -on the basis of the numerous protests received from different sides about the relational logo “RoMe & You”- restored the emblem with the ‘acronym SPQR, canceling the logo proposed during the government of Ignazio Marino (www.iltempo.it). To those who asked him if “RoMe & You” will no longer be used he replied: “The logo that Rome has always had will be used”.

This decision encourages a reflection on the effectiveness of re-branding in particular circumstances. In fact, some symbols are so popular, loved and communicative that nobody wants to change them. This also applies to some corporate brands that are now recognized by the public as distinctive features of global companies. For example Coca Cola, Nike or Disney (www.crearelogo.it).

In fact, according to the social discourse developed on the web, the Rome relational logo seems not to have brought added value to the solid image already present. In fact, it turns out that the “chromatic bubbles” placed above the red shield - created to indicate key elements of the city like the round shape of the Colosseum, the round shape of pizzas, the round (spherical) shape of ice cream (www.underconsideration.com) - have been not very easy to decode and have been assimilated to the city holes or to the “carnival confetti” (www.romatoday.it).

The President of the XV Town Hall Daniele Torquati summarizes the controversy on Facebook in February 2015 as follows: “Those colored carnival confetti instead of the crown, the Cross and SPQR - they claim - denote little knowledge of the reasons why Rome and its history are known in the world. Above all, Rome is Rome across the globe from China to North America. Who knows how many months the Capitol scientists have used to give birth to such a dazzling logo. For millennia SPQR has never been canceled, they say” (romafanpage.it).

The choice of the “return to the past”, to the timeless red shield, would have agreed Romans and politicians who had expressed polemical representations towards the logo proposed during the Marino Government (Mayor of Rome with the support of a centre-left alliance in 2013-2015) and, even before that, also towards the one born during the Giunta Alemanno (Mayor of Rome for the centre-right during the period 2008-2013).

Moreover, in the corporate environment, such changes have also been adopted by private companies, which, following the protests of the customers, have returned in some cases to the old logo. Cfr. for example the GAP logo or the Benetton Company -that had a return to the past, rather in terms of advertising-. Following a long period characterized by a communication that remained famous for the numerous scandal advertisements, which led to an increase in social discourse for years and also a strengthening of the brand, the company - after the umpteenth provocation that had a huge media impact and different protests from the public- dissolved the “marriage” with the famous creative photographer Oliviero Toscani and chose to return to traditional images, moreover more in line with the company philosophy “all united in the name of Benetton” (United Colors of Benetton) (de Rosa & Bocci, 2013b).

Coming back to the ten European Capitals, finally, London opted for re-branding, while Vienna has only updated the payoff from “now or never” to “now forever”.

The Iconic Social Representations for Destination@-Branding

10

Question 4: In light of the wider research programme, how is the symbolic power of institutional stems and commercial logos articulated in the complex scenario of the Destination@-Branding?

In order to furnish a first overview of the role of the main graphic element of branding, in the framework of the more complex research programme, here we summarize some results (de Rosa, Bocci & Dryjanska, 2019) related to the analysis of the institutional tourist websites (brand identity) and forum discussion on the TripAdvisor portal (brand image).

Each city under scrutiny can be positioned according to the similarities/differences between the social representations of the top places communicated via institutional tourist websites (assumed as vehicles of brand identity) and the free spontaneous conversations of online communities (assumed as vehicles of brand image).

For Berlin, there was the closest coincidence between the “Top Places” (7 out of 10) identified by the institutional tourist websites (assumed as vehicles of the city’s brand identity) and by the TripAdvisor online community members (assumed as vehicles of the city’s brand image).

For Helsinki and Rome three places out of 10 coincide; for Madrid, Brussels, Lisbon and Paris two places out of 10 match, for Vienna and London only 1 out of 10, none for Warsaw.

Three cities (Berlin, Helsinki and Rome) stand out among the others; they are profoundly different from each other, but their differences converge in terms of a preliminary analysis of *destination@-branding*. On the one hand Berlin has followed the line to make the history a protagonist accessible to its visitors.

For Rome the artistic-architectonic dimension plays an important role in terms of convergence of brand image and brand identity.

On the other hand, Helsinki is the capital that, from the point of view of communication via Internet, is least focused on cultural history but instead emphasizes other aspects, such as socio-recreational dimensions.

For these three cities, this research has highlighted distinct “landmarks” like the “Reichstag”, as well as other places of memory in the case of Berlin; the “Trevi Fountain”, “Vatican” and “Villa Borghese” in that of Rome; and “Helsinki Zoo” and “Linnanmäki amusement park” as socio-recreational places in the case of Helsinki.

Despite their differences, these three capitals converge in the importance assigned to specific Top Places, demonstrating that destination@-branding is emphasised via this iconic component of social representations of cities (the landmarks).

In this scenario, actually, Rome, Helsinki and Berlin do not fully benefit from the commercial logo: Rome because of the constant changes that seem to echo political developments; Helsinki being in the middle of a well-argued transition phase; Berlin, following the results of this research, is placed on the lowest positions compared to the attitudes of the participants towards the brand, but has not yet invested in re-branding.

In the awareness of the volatility of research data, the survey in longitudinal perspective will be able to study the echoes of the transformations (in light of the Social Representations Theory) currently underway also for: Lisbon, whose commercial logo had detected some critical issues; Paris that although it has adopted a new logo has continued to focus on the Eiffel Tower; Brussels that has decided to delete multi-colored bars evoking multi-ethnicity.

Instead, the position of Madrid (not rebranded) can be considered strengthened by the results of this research in terms of attitudes of the participants.

Finally, in this summary scenario Vienna, London and Warsaw do not appear to be particularly strengthened by the commercial logo. Indeed, only London opted for a complete re-styling of the brand -whose representations could be analyzed in further studies- while Vienna only changed the payoff and Warsaw left the logo unchanged. However, both these last ones could have benefited from an adequate and consistent re-branding.

RECOMMENDATIONS

In proposing recommendations, however, as discussed above, it should be noted that the changes often become the subject of a polemical social discourse that is increasingly divided over the Internet (especially websites, blogs and social networks) and can even last for years, as was the case for commercial logos used in this research related to London (on the websites of Moving Brands and London and Partners) and Rome (blog.adci.com; www.06blog.it; www.tgcom24.mediaset.it).

The controversies triggered by the web show that: touching iconic symbols generates more controversies than replacing words, as de Rosa learned investigating the controversial representations provoked by the change of the logo of the Italian Communist Party (P.C.I.) (de Rosa & Farr, 2001; de Rosa, 2014).

The symbols seem to possess the power of materialising the deepest dimension of the figurative nucleus of the social representation. More specifically, some of the elements that can be included under the label “brand element mix” possess, as Rouquette noted (1994), the following properties:

- they embody the emotive dimension of the central nucleus of a social representation -dimension defined by the author with the term “nexus”-;
- merge denotation and connotation;
- reify (objectify) a system of cadences and values;
- are hard to modify through analysis and rational reflection;
- constitute a system of communication relatively independent vis-à-vis that of the discourse. (...)

In the symbolic order, in fact, to act on the symbol of a person or of an object, means to act on the person or on the object itself. To strike the symbol means to strike directly the entity that it represents (de Rosa & Farr, 2001; de Rosa, 2014).

FUTURE RESEARCH DIRECTIONS

Given the continuous evolution of some of the commercial logos, like the logo of Rome discussed above, the future research should include the new logos and compare them with the previous ones. Moreover, starting from the preliminary analysis of the iconic social representations for Destination@-Branding, presented here, the results obtained by analyzing the institutional and commercial logos as elements of the “brand element mix” should be further re-read together with the more comprehensive data concerning the divergence/convergence of the City@-brand identity and City@-brand image, including:

- virtual City brand identity (Aaker & Joachimsthaler, 2000) created by marketers through institutional websites (de Rosa et al., 2012, 2013) and institutional tourist websites (de Rosa & Bocci, 2014) of the ten European Capitals;

- virtual City brand image (Cai, 2002; Keller, 1998) shared via commercial sites like Tripwolf and Booking.com, spontaneous conversations and exchanges of experience among the members of Social Networks like Facebook and Yahoo Answers, Twitter, Instagram and YouTube, portals like TripAdvisor, which are employed as a vehicle for dissemination of common sense knowledge (de Rosa & Bocci, 2014).

CONCLUSION

Following the hypotheses, the main differences between stems and logos emerged through the use of the ad hoc grid that showed the divergences in the structural elements of stems and brands (hypothesis1) and also through the calculation of the indexes of polarities that allowed us to detect a more positive attitude towards commercial logos than towards institutional stems (hypothesis2).

On the contrary, shared contents between stems and logos have been found -for example- referring to:

- the “history” - the “Second World War” in the brands of Berlin and Warsaw and the “colonialism” in the brand of Lisbon.

Concerning commercial logos, especially the “emotional” and “value-related” dimensions affected in the opposite way (negative vs positive) the social representations:

- negatively: in the cases of Warsaw and Lisbon (sadness);
- positively: in the cases of Brussels, Paris or Madrid (happiness).

The polemical social discourse activated among citizens confirms: the dynamic of resistance/acceptance in the social representations provoked by changes related to their symbolic and iconic dimensions; the interest for investigating the social and communicative phenomena related to the iconic narratives about cities evoked by the brands and the city destination@-branding” (Bocci, de Rosa, & Dryjanska, 2017).

Besides their descriptive value and possible function in guiding city’s institutional and tourist communication managers, the results have a historical value with respect to the evolution of the Institutional communication, assuming a particular interest for further comparative analyses (de Rosa & Bocci, 2013a; de Rosa, Bocci & Picone, 2012) concerning the specific component of the brand element mix (Cai, 2002), here analytically described through structured and projective tools aimed at identifying both the structural (distinctive elements) of the brands and the structure, contents and polarities of the social representations associated with them.

This study is part of a more general attempt to deal with the complexity of the new communicative web scenario based on multi-channels, assumed to be influential for the genesis, transmission and negotiation of the social representations of Capital Cities. The policy makers should therefore take into account social representations and test innovative design ideas in order to verify that a new logo for example includes elements considered as essential in how people represent a city.

KEY TERMS AND DEFINITIONS

Associative Network Technique: A tool developed by de Rosa of projective nature used in order to study the Social representations of iconic and verbal stimuli, by considering structure, contents, and attitudinal dimension of a semantic space.

Destination-Branding: An articulation of different interrelated components: brand identity, brand image, and brand element mix.

Destination@-Branding: Extension of the concept of destination-branding to the digital world of the Internet, including websites, social networks, portals, etc.

Index of Polarity: An index created by de Rosa aimed at detecting the evaluative component of social representations, on the basis of the polarities (positive/negative) attributed to the words associated by the subjects to the stimuli.

Modelling Approach: A paradigmatic approach to Social Representations developed by de Rosa that integrates different methods and techniques coherently with the articulation of different theoretical constructs and dimensions.

Nexus: The emotive dimension of the central nucleus of the social representations.

Social Representations: Naïve theories of common sense that express systems of values, convictions and norms of behavior, with a double function of organizing the perception of the world and serving as a shared system of social communication and interpersonal exchange.

Rapid Changes in Approaching First-Time Destination Historical Cities

INTRODUCTION

The Internet is rapidly changing the way first-time visitors approach a new urban destination. On the one hand, new media influence public spaces and infrastructures (Puel & Fernandez, 2012) but they also play a crucial role in how a person perceives a city prior to the direct experience.

European Capitals are well-established destinations among visitors from different countries who arrive with some preconceived ideas and various expectations that affect their behaviour during the visit.

According to Kalandides (2011, in Castillo-Villar, 2018:33): “The city’s image blends and simplifies all the tangible and intangibles elements that relate to the city. The image is formed from the encounters that we have with the messages communicates the city. These messages can be taken from the media, the culture or the direct experience”.

Moreover, for Castillo-Villar (2018:33): “Each individual forms his or her own particular city’s image, but also shares collective images due to a common physical and cultural environment. Therefore, city branding should focus on these public images to project an image true to the values, beliefs and ideas shared by locals and visitors.”

In order to understand the images of urban social space, the theory of social representations (Moscovici, 1961/1976; 1984) has over the years offered an efficient framework. How is it changing in the era of readily accessible Internet-based sources? This chapter attempts to answer this question by taking into account the diversity of Internet-based sources of information about three European Capitals: London, Madrid and Warsaw, including the voice of those who visit a city for a limited period of time. Based on feedback from the field studies conducted in European Capitals, a special consideration is given to specific ways of exploring the destinations prior to the visit, such as turning to Institutional websites, social networks and Google Earth. While some of these tools have been examined in the context of urban studies (Diekmann & Cloquet, 2012; Porta et Al., 2014; Zhou & Wang, 2014; Fierro et Al., 2015), an integrative framework to consider Internet-based resources that shape social representations of cities has not been proposed yet. The aim of this contribution is the development of a new classification of sources of information, reflecting the complexity of tools available to city users today.

DOI: 10.4018/978-1-7998-3473-1.ch117

THEORETICAL BACKGROUND

Within the theoretical framework of social representations (Moscovici, 1961/1976; Farr & Moscovici, 1984; Moscovici & Duveen, 2000; de Rosa, 2011; 2013a; Sammut et Al., 2015; Lo Monaco et Al., 2016), this chapter features the web-based multi-faced sources of information about three European Capitals: London, Madrid and Warsaw.

The social psychological construct of social representations introduced by Moscovici (1961/1976) has been successfully applied to urban studies since decades. Milgram (1984) conceptualised cities as social representations, attributing as much importance to the characteristics of neighbourhoods' residents as to physical features of places. Subsequently, the construct of social representations has been used to explain how urban entrepreneurs influence perception of the city to their convenience (Hubbard, 1996). In urban context, the theory of social representations provided a more complex manner of considering residents' attitudes towards tourism (Andriotis & Vaughan, 2003). However, in the contemporary hustle of European Capitals it becomes increasingly common to find more tourists or commuters than actual residents, at least in some areas. In fact, for years the theory has also been applied to study how tourists represent cities as a whole as well as specific places or urban areas before and after the visit (de Rosa et Al., 1995; de Rosa, 1997, 2013b; de Rosa & D'Ambrosio, 2011).

First-time visitors form an especially interesting population, particularly useful when studying the city's image (Richards & Wilson, 2004), due to the fact that their knowledge about a destination stems from multiple sources of information, excluding direct physical experience. Quite often interpersonal communication plays a crucial role in enticing potential visitors to see a new city with their own eyes, as they seek referral from repeat visitors (Chi, 2012). While exploration tends to be the dominating tendency of first-time visitors, as opposed to acquisition preferred by repeat visitors (Lau & McKercher, 2004), such exploration begins prior to the trip and occurs through numerous channels. From conversations with family and friends, through consultation of newspaper articles, books and other printed and audio-visual materials such as movies, a potential visitor seeks information in an active way.

Today, the Internet offers numerous sources of information about cities. Concerning modern technologies and differentiation between specific forms of Internet-mediated communication in urban context, there have been some studies related to exploration of cities with Google Earth (Porta et Al., 2014), including the presence of places of interest in the satellite imagery (Zegras et Al., 2012); however, the relevance of this particular tool for social representations has not been discussed. In the era of Internet -where an integrative framework to consider Internet-based resources that shape social representations of cities has not been proposed yet- the paper furnishes an overview of the online city brand identity (Aaker, 1996) and image (Pike, 2009) of the European Capitals online. Overcoming the weaknesses regarding the literature focused solely on cognitive and evaluative factors in perception (processes of categorization, encoding, storage and retrieval of information in memory) the added value of this study is to re-read these constructs through the comprehensive multi-dimensionality of social representations (Vanolo, 2010). Moreover, in valorising the identity-related dimension of the cities, it refers to Proshansky's (1978) definition of place-identity as a sub-structure of self-identity characterized by clusters of cognitions, memories and affections concerning experienced places. The importance of the intersection between the constructs of the place-identity and the social representation of the European Capitals has been discussed by de Rosa (1997, 2013b).

APPROACHING FIRST-TIME DESTINATION HISTORICAL CITIES

10

This paper presents selected results of a wide research project dedicated to social representations of European Capitals, which began more than twenty years ago and still continues today (cfr. Inter alia: de Rosa, 2013c; de Rosa, Dryjanska & Bocci, 2017).

The methodology has been inspired by the modelling approach to social representations (de Rosa, 2013a,b; 2014), based on the integration/differentiation of multi-theoretical constructs and multi-methodological research designs, coherently justified beyond the simple sum of various techniques.

The modelling approach is aimed at grasping the core value of the social representations as a unifying meta-theory in the social sciences, by operationalizing the investigation of any object of this supra-disciplinary field in multi-methodological research designs. The diverse techniques of data collection (structured and projective, textual and figurative, verbal or behavioural etc.) and even the choice of the data analysis strategies require adequate complexity depending on the multi-theoretical perspective adopted and the variety of constructs selected (representations, identity, social memory, emotions etc.) and full justification with regards to the specific hypotheses, also related to the expected results depending on the different techniques employed and their communicative channel.

The research starts from the first line of the field study -involving 420 first-time visitors from 7 countries, contacted before and after their first-time visit- and compares the results with those from the second interrelated line on the media study.

A set of three hypotheses concern each considered web-based media source: a) Institutional websites; b) social networks; c) Google Earth (de Rosa, Bocci & Picone, 2013; de Rosa & Bocci, 2014) and its relationship with more traditional forms of communication (de Rosa, 1997; 2013c). The communicative capacity of the Institutional websites and the manner of creating virtual itineraries by Google Earth are related to the overall self-rated importance of sources of information about cities; while exchanges about the same target cities through social networks reflect the interactive nature of interpersonal communication.

METHODOLOGY

The results of the field study are extracted from data collected in London, Madrid and Warsaw between 2011 and 2013 by 420 first-time visitors from the following countries: France, Germany, Italy, Poland, Spain, United Kingdom and U.S.A. Each respondent was selected according to the main criterion “to visit the city for the first time”. Contacted using the snowball sampling technique, the participants - on a voluntary basis - filled out questionnaires in their native language, starting from socio-demographic information, reason of residence in their current location and the additional reasons for visiting the city apart from tourism (study, work, etc.). Concerning gender, two thirds of participants are women in case of each city. According to age, the research participants have been categorized in three groups: less than 26 y.o.; 26-40 y.o.; 41- 60 y.o. The average age was 27 for London, 26 for Madrid and 34 for Warsaw.

The participants have been contacted before and after their first-time visit to the city, approached through travel agencies, language schools, professional associations and using the snowball sampling technique, a tool for finding research participants. According to this technique, one subject gives the researcher the name of another subject, who in turn provides the name of a third, and so on (Vogt, 1999); like a rolling snowball, initially selected research participants contribute to recruit future subjects from among their acquaintances.

As far as it concerns the media studies, the “Institutional website identity” has been explored, to convey the city-brand identity through Institutional websites. Comparative analysis of the Institutional websites of the three European Capitals (www.london.gov.uk; www.munimadrid.es; www.e-warsaw.pl) has been conducted starting from the assumption that the websites constitute official ‘business cards’ presented by the municipalities to residents and tourists.

Moreover, the study explores various forms of technologically mediated information available on the Internet. For the Institutional websites the Usability Test (Nielsen & Loranger, 2006) has been performed (de Rosa & Bocci, 2014); subsequently, the content analysis has been applied, with the grid designed by de Rosa & Picone and the ATLAS.T software (de Rosa, Bocci & Picone, 2013).

H1: The first hypothesis predicts a positive relation between the importance of different sources of information indicated by the first-time visitors (field study) and the degrees of usability and overall communicative capacity of the websites (media study).

H2: From the top-down approach it is possible to move into an interactive communication of social networks, considered as a contemporary form of interpersonal mediated communication. Therefore, it is expected that the social representations of the most important places in the cities (field study) will correspond to those evoked in the social networks, Facebook and Yahoo!Answers (media study). The results of interpersonal communication through the social networks concerning places have been analysed using descriptive statistics and Lexical Correspondences Analysis with SPAD software. The Correspondences Analysis makes it possible to identify hidden dimensions that are subtended to the data and summarizes the relations between original variables. The aim is to simplify interpretation of the whole range of information through a synthesis, so that newly identified dimensions (factors) could represent a good approximation of the starting data-matrix. Among the indicators useful for the interpretation of the results of Correspondences Analysis - as far as it concerns the first two factors extracted by SPAD - the following are taken into account:

1. the absolute contribution (a.c.), which constitutes the part of the total inertia of the factor explained by each variable;
2. the relative contribution (r.c.), or cosine squared, which assesses the contribution the factor provides to the explanation of the variability of each modality.

H3: Finally, the third hypothesis regards a relationship between the level of information about a city (field study) and the manner of virtual exploration of it using Google Earth (media study). According to this hypothesis, the less known the city among first-time visitors, the more variations it is possible to expect in the itineraries between low and high level of information enabled in the software settings. In this last task the participants were asked to create an itinerary of a city in Google Earth with a low level of information, succeeded by a high level of information. The results of this virtual exploration were assessed by content analysis and descriptive statistics.

The aim of this chapter, enriching the classification of sources of information about an unknown city, thanks to a thorough consideration of the Internet, is based on the premise that technologically mediated communication plays an ever-increasing role in the genesis, transmission and transformation of urban social representations.

PRESENTATION AND DISCUSSION OF RESULTS

10

The results of the field study in London, Madrid and Warsaw focus on the increasing role of the Internet as a source of information and therefore a major factor in shaping social representations of European Capitals. Interpersonal information, even when transmitted using modern technologies, tends to be very significant, especially in case of close ties such as kin and friends (Mok, Wellman & Carrasco, 2011). In fact, the participants of the field study have attributed the highest importance to the interpersonal communication, while the Internet appears as the second most important source of information.

Based on this finding, the research further explores different ways in which the Internet contributes to shaping social representations of contemporary urban settings, through: Institutional websites (H1), social networks (H2) and Google Earth (H3).

On a scale from 1 to 10, on average the participants of the field study have attributed the highest importance of the Internet to information about London followed by Madrid and Warsaw.

The social representations reflected in the overall average self-rated importance of various sources of information about cities have been compared with the communicative capacity of the websites of the three European Capitals.

While more details and information about additional European Capitals have been reported elsewhere (de Rosa & Bocci, 2014), the concise results of the analysis of Institutional websites under scrutiny are summed up in the following paragraphs.

Although overall the Institutional websites do not appear highly attractive from the point of view of usability, there are some clearly marked differences between the three cities:

- London. The Institutional website emphasizes innovation and dynamics concerning urban services, in particular transportation and sports. In the contemporary scenario of the on-going financial crisis, attention has been given to leadership in business, work opportunities and competitiveness. While many clear and useful solutions have been proposed to Londoners, from the perspective of visitors, especially those coming from abroad, the website appeared somewhat self-referential. Concerning images available on the home pages, London's municipality offered dynamic photos corresponding to the highlighted topics.
- Madrid. Imbalance in favour of residents has been detected in the Institutional website of Madrid. Nonetheless, it demonstrated a medium-high level of reliability and a fairly well developed content, although overall usability was rated as medium-low. Concerning images available on the home pages, Madrid promoted itself using static photos focused on nature.
- Warsaw. The Institutional website of Warsaw displays the highest discrepancy between usability and reliability. The content appeared as the least complete, although quite highly aimed at visitors, with special attention paid to cultural events. Concerning images available on the home pages, Warsaw promoted itself using static photos focused on monuments (Royal Castle). According to Michaelidou et Al., (2013), it would be more advantageous to use holistic images of the destination that better reflect the preferences of city users, based on online visitor-generated photography.

On the whole, London's website had the highest communicative capacity, followed by those of Madrid and Warsaw. This is the same order observed when comparing the overall average self-rated importance of information about these three Capitals. Therefore, the hypothesis concerning correspondence between the results of the field study and analysis of the Institutional websites has been confirmed (H1).

Just as interpersonal communication is considered highly credible and therefore important, social networks tend to be perceived in a similar manner (Ayeh et Al., 2013). In order to be able to compare the results of the field studies in London, Madrid and Warsaw with the results of conversations available on Facebook and Yahoo!Answers, the following paragraphs focus on the “places”:

- London. The data related to the most meaningful and frequently mentioned places prior to the visit (field study-Figure 1) resemble the data from social networks. As a result of Lexical Correspondences Analysis of social networks, the main two factors explain the organization of social representations of the most important places in London. This can be clearly observed taking into account the example of Buckingham Palace, one of the most significant places before the visit (but not after it –field study) and in the social networks (where it is present with high frequencies of $f=37$ –dim.2 a.c. 3.8 r.c. 0.14- together with: Piccadilly Circus $f=44$ –dim.2 a.c. 1.9 r.c. 0.17-; London Eye, $f=36$ –dim.2 a.c. 3.1 r.c. 0.10-; Westminster $f=35$ –dim.1 a.c. 1.1 r.c. 0.33- and Trafalgar Square $f=28$ –dim.2 a.c. 1.2 r.c. 0.17). Direct experience therefore manifests itself as a factor that shapes social representations in a different way than the interpersonal communication, whether traditional or mediated by technology.

Figure 1. The most important places in London before and after the visit

- Madrid. For Madrid an opposite trend has been detected: the places mentioned after the visit (field study-Figure 2) appeared as much more similar to those mentioned in social networks (media study) where specific places are present with high frequency: Puerta del Sol ($f=32$) –dim.2 a.c. 0.3 r.c. 0.04-, Parque del Buen Retiro ($f=27$) –dim.2 a.c. 3.6 r.c. 0.18-, Palacio Real ($f=24$) –dim.2 a.c. 3.0 r.c. 0.16- and Atocha Station ($f=5$) –dim.2 a.c. 0.3 r.c. 0.16-. All of them gained importance as a result of direct experience. Unlike for London, places mentioned after the visit had much more in common with the social networks than those indicated prior to the visit.

Figure 2. The most important places in Madrid before and after the visit

This finding could suggest that social networks can play an active role in shaping urban social representations, not only as a source of communication, but also as a transformative agent in a way similar to direct experience, due to their capacity to build on actual experiences of the users much more than Institutional websites, for example.

- Warsaw. For Warsaw, first-time visitors enlisted a high number of specific monuments and parks, paying attention to the history and patriotic aspects; on the contrary, the Capital has been mentioned in a brief manner in the social networks (f=17 in total, including only: Castles, Old Town, Palace of Culture and Science, Palace on the Water). Facebook and Yahoo!Answers users have

mentioned many more generic places, such as palaces, districts and shops than in case of other cities; therefore, the comparison with the field study data would not be appropriate in the same way as in case of London and Madrid.

Concluding, the second hypothesis -related to the correspondence of the social representations of the most important places in the cities with those evoked in the social networks Facebook and Yahoo!Answers- has been only partially confirmed. While in case of London and Madrid it has been possible to verify such correspondence, the city of Warsaw constituted an exception (H2).

As already stated, the overall self-rated importance of sources of information has been the highest for London, lower for Madrid and the lowest for Warsaw. According to the third hypothesis, for less familiar cities the differences between high and low level of information enabled in the software settings shall be greater than for more familiar ones. The research presents the most frequent itineraries consisting of ten places proposed for each city in two different modalities: low level of information (only basic view available) and high level of information (images, Panoramio and information from Wikipedia available to users).

- London. The places enlisted for London in both modalities are identical and include: Natural History Museum, Buckingham Palace, Westminster, Big Ben, London Eye, Tower Bridge, London Tower, British Museum, Madame Tussauds and Camden Town.
- Madrid. For Madrid, with a low level of information set in Google Earth the participants most frequently chose the following sequence: Puente de Toledo, Centro de Arte Reina Sofia, Museo Thyssen-Bornemisza, Parque del Buen Retiro, Alcala Gate, Circulo Bellas Artes, Plaza Mayor, Plaza de Oriente, Palacio Real and Estadio Santiago Bernabeu. The high level of information has an influence on the choice of places included in the virtual itinerary in the following order: La Latina, Palacio Real, Tempio di Debod, Plaza de Espana, Gran Via, Plaza Mayor, Circulo Bellas Artes, Museo Thyssen-Bornemisza, Parque del Buen Retiro and Plaza de Toros. The two itineraries have in common only five out of ten places, which demonstrates a much stronger influence of Internet-based sources of information enabled through Google Earth than in case of London.
- Warsaw. The first-time visitors who participated in the field study have assigned the lowest self-rated overall importance of various sources of information about Warsaw. In line with the hypothesis, this has affected the differences between virtual itineraries proposed in Google Earth in high and low modalities. The first difference concerned the form of the most frequent itineraries, which changed from linear to a combination of linear and circular. Moreover, the list of places has changed, since in the first modality the participants proposed the following places: Ghetto, Old Town, Royal Castle, University of Warsaw, National Stadium, Three Crosses Square, Lazienki Park, Palace of Culture, Monument to the Unknown Soldier and National Opera House. In the second modality the places were: Sigismund's Column, Royal Castle, Mermaid Statue, Barbican, Our Lady's Church, Monument to the Heroes of the Warsaw Uprising, Royal Route, University of Warsaw, Palace on the Water and Chopin Statue. Only two out of ten places remain the same in both modalities. It is also possible to notice that with more information available, such as images, participants tend to focus on single monuments rather than areas, for example Sigismund's Column and Mermaid Statue are both single monuments in the area of the Old Town, just like the Palace on Water and the Chopin Statue are located in the Lazienki Park mentioned in the first modality.

The third hypothesis has been verified. According to it, a high level of information from different sources, as observed among first-time visitors to London, strongly influences decision-making when planning a virtual itinerary, similar in both modalities. On the other hand, for Madrid and Warsaw the virtual itineraries proposed display important differences depending on modality, since the self-rated level of information about these Capitals tends to be much lower among first-time visitors. (H3).

RECOMMENDATIONS

Assessing how social representations are generated, transmitted and transformed in this particular virtual environment may certainly be useful to policy-makers. This chapter proposes a well-tested model of the relationships among results and offers some practical implications of findings from the point of view of urban governance (Graham & Aurigi, 1997; Edwards, Griffin, & Hayllar, 2008).

FUTURE RESEARCH DIRECTIONS

The research can be extended by further comparisons between field studies and media studies related to other historical Capital cities under scrutiny -Rome, Paris, Berlin, Brussels, Helsinki, Lisbon and Vienna-, also including more articulated focuses on the composite world of Internet and its multiple environments, contributing to the reconstruction of brand image (Pike, 2009) like Booking.com, Twitter, Instagram, YouTube and TripAdvisor as vehicles for dissemination of common sense knowledge (de Rosa & Bocci, 2014). Moreover, certain mobile phone applications or blogs, which constitute a fertile material of analysis (Magnini et Al., 2011, 2012) can be included.

Reinterpreting the construct of destination branding in terms of destination e-branding under the “umbrella” of the social representations of European Capitals, it is possible to stress the interest of considering diversified multi-channel communicative tools in the Web 2.0 scenarios as asynchronous vehicles of the virtual city brand identity/image, which co-construct social representations of symbolic and historically embedded realities, such as the European Capitals. The comprehensive study is an attempt to deal with the complexity of the new communicative web scenario based on multi-channels, assumed to be influential on the genesis, transmission and negotiation of social representations.

CONCLUSION

The aim is to demonstrate links between such sources and traditional means of communication, overcoming the model where the Internet is positioned on the same level and analysing it in a parallel way. According to the modelling approach to the study of social representations applied in environmental psychology in urban social context (de Rosa, 2013b) each hypothesis – in this research three – determines the most appropriate tools and techniques of analysis. Combined, they reflect social representations of cities examined from different angles.

As a result it is possible to propose a new model (Figure 3).

This model can be further extended to consider other Internet-based sources of information about cities, which influence their social representations.

The results demonstrated that:

Figure 3. Sources of information about a city with a special focus on the Internet

- 1) The Internet has become one of the most important sources of information about the cities;
- 2) Among the three Institutional websites under scrutiny, the website of London has the highest communicative capacity;
- 3) There is a positive relationship between the self-rated importance of different sources of information and the communicative capacity of the Institutional websites of the three cities (H1);
- 4) There is a correspondence between the field studies conducted in London and Madrid and the social representations of the cities detected when analysing the social media (H2);
- 5) The Internet influences the social representations of urban social space, especially in cases of Madrid and Warsaw, when the self-rated level of information about these Capitals tends to be much lower (H3).

The Internet is rapidly changing the way first-time visitors approach a new urban destination. As the research demonstrates, the multiple digital worlds of Internet play a crucial role in how a person perceives a city prior to the direct experience. Moreover, they can shape urban social representations, not only as a source of information, but also as a transformative agent in a way similar to direct experience, due to their capacity to build on actual experiences of the users.

These results show the strength of the modelling approach; its capacity to integrate in an organized rationalized and justified way various methods coherently with the multiple theoretical constructs that social representation pretends to articulate, when compared with the fragmentation of the micro-paradigms in the mainstream social psychology tradition.

The local governments of European Capitals should take advantage of the sources of information in order to meet the increasing demand for genuine and creative cultural tourism by implementing “landscapes of creativity” (Russo & Sans, 2009).

KEY TERMS AND DEFINITIONS

European Capitals: Capital cities in Europe, which include an area that can be identified as a historic center (sometimes called “Old Town”, like in the case of Warsaw).

First-Time Visitors: People who visit a given place (for example a city) for the first time in their lives.

Geo-Cultural Context: Specific geographic location that takes into account the cultural characteristics of inhabitants, such as common language, history, customs or art; for example, insular, Mediterranean or North-European geo-cultural contexts.

Modelling Approach: A paradigmatic approach to Social Representations developed by de Rosa (2013a, 2013b).

Social Networks: In the definition of social networks, inter-relationality among diverse social actors, such as individual private users and organizations, is a core element.

Social Representations: A complex construct created by Serge Moscovici (1961), which, according to de Rosa (1994), can be operationalized on three different levels: a) social representations as a phenomenon; b) theory of social representations; c) meta-theory of social representations.

Urban Tourism: A form of tourism aimed at visiting a city while traveling for recreational purposes.

An Exploratory Study of In-Flight Safety Videos and Airline Marketing Strategy

INTRODUCTION

In today's modern world, traveling has become more common. With the emergence of social media platforms such as Instagram and Snapchat, air travel has increased tremendously in recent years as travelers share first-hand experiences online (Borgogna, 2016). In the aviation industry, a government entity known as the Federal Aviation Administration (FAA) ensures passengers' safety as a top priority. In an effort to promote safety awareness to the passengers, the FAA mandated the commercial airlines to present passengers on board with an in-flight safety video. The in-flight safety video is a pre-recorded video that explicitly presents safety instructions and procedures aimed to be delivered to passengers onboard.

Passengers have often reported these pre-safety briefings to be considered boring and repetitive, and are sometimes ignored (Seneviratne & Molesworth, 2015). This presents the argument that numerous airlines have considered and have therefore transformed their safety videos into more interesting means to attract passengers' attention, such as Air New Zealand (Plautz, 2016). However, recent trends from commercial airlines such as Air New Zealand and Virgin America have attracted millions of YouTube views through their pre-flight safety videos, encouraging viral marketing (Plautz, 2016). This begs the question as to whether airlines are incorporating entertaining content to the in-flight safety video to market their own airlines, or for passenger information retention purposes. As such, the objective of this chapter is to explore in-flight safety videos presented to passengers as a form of marketing, for numerous airlines ranging from premium to budget airlines. The remainder of the chapter includes the background of the in-flight safety video, addressing varying perspectives from the academic literature, followed by research methodology, contribution, and managerial implications.

BACKGROUND

Relationship Between In-Flight Safety and Customers

Customer retention is certainly a priority for many industries. For the aviation industry, factors such as a customer loyalty program, satisfaction, reliability, and perceived risks are important determinants of customer retention (Climis, 2016; Atalik and Ozel, 2007; Johnson; Garbarino and Sivadas, 2006). Climis (2016) suggests that a positive relation exists between perceived safety and satisfaction and that the reputation of the airline in terms of safety, and cabin crew knowledge were key elements for customers to

DOI: 10.4018/978-1-7998-3473-1.ch118

repurchase and fly with the specific airline. This result is also consistent with related studies conducted earlier (e.g. Atalik and Ozel, 2007; Johnson, Garbarino and Sivadas, 2006).

Previous studies highlight various major problems in aviation safety such as equipment failure, weather conditions, unfastened seatbelt during turbulence, pilot error, air traffic control, cabin crew error, other aircraft collision, terrorism, or unknown (Oster Jr et al., 2013; Lofquist, 2010; Madsen, 2013). Madsen (2013) suggests that a positive link exists between safety risks and profitability when examined the US aviation industry. Aviation safety is an integral part for all concerned stakeholders, particularly passengers and cabin crew. As such, a recent study has looked into virtual reality (VR) as a method of knowledge transfer, specifically safety aviation instructions (Chittaro et al., 2018). The VR tool is proposed to be delivered on smartphone or mobile devices. The use of the mobile VR tool was also compared to the traditional briefing card. Results of the study show that knowledge transfer was significantly faster, more effective, and more accurate when participants used a less traditional tool (Chittaro et al., 2018). This is of great importance since the real-world application of safety knowledge is a fundamental survival factor in a life-or-death situation (Chittaro et al., 2018). Aviation safety is also associated to cabin crews' perceptions of safety culture (Sexton & Klinect, 2017). A study in the field of psychology suggests that a happy crew, with a positive perception of the safety culture are considered safer and less likely to conduct errors. This places emphasis for training departments to ensure teamwork, leadership skills, open communication, and less stress on performance are laid out to pilots and cabin crew to enhance the safety culture (Sexton & Klinect, 2017).

It is an important consideration for the aviation industry to understand what factors are taken into account for travellers in deciding which airlines to fly with. An econometric study was conducted using surveys to measure young travelers' flight choice (the average age of participants was 22 years old). The first questionnaire was generally asking which factors were most important to young travelers. It was found initially that young travelers did not take aviation safety as a factor in their decision making, but price was (Koo et al., 2015), which is contradictory to another study which stated that safety is ranked 7th and 8th for low-cost and budget airlines (O'Connell & Williams, 2005). However, when participants were prompted using a novel approach which specified four important factors: number of incidents (safety), price, flight duration and inflight service (food, entertainment, cabin crew service), safety then became a significant factor in decision making, particularly when risks are involved (O'Connell & Williams, 2005). Therefore, researchers suggest that there is a need for marketers to include safety as an important outline to advertise airlines (Koo et al., 2015, O'Connell & Williams, 2005). Although safety is a major key factor in customer satisfaction with airlines, passengers' perception of safety as an important factor differs from one passenger to another, especially between leisure and business travelers. Leisure travelers are more greatly concerned with safety perception of commercial airlines than business travelers (Ringle et al., 2011) leading to another implication for airlines to strengthen marketing activities involving safety aspects for the general public specifically leisure travelers (Ringle et al., 2011).

In-Flight Safety Requirements

Federal regulators such as the Federal Aviation Administration (FAA), and the Australian Civil Aviation Safety Authority (CASA), place a large focus on in-flight safety. In-flight safety instructions were traditionally delivered verbally by the cabin crew to the passengers on board. This practice still occurs in low-cost airlines that do not provide the technology such as screens onboard. Along with federal regulatory bodies, the International Civil Aviation Organization (ICAO), United Nations specialized agency, aims to work closely with its members in order to coordinate assistance among members in the aviation

civil sector industry. The ICAO has also set Standards and Recommended Practices (SARPs) adopted by the Council of the International Civil Aviation Organization. There are a set of standards that is expected for airlines to comply with. The International Civil Aviation Organization has set required messages that is mandated to be covered in any commercial flights' safety briefing (Seneviratne & Molesworth, 2015; "Pre-flight safety demonstration", 2014):

- the locations of emergency exits
- the attentiveness to emergency floor lighting
- the use of the seatbelt and adherence to the fastening of seatbelts during turbulence
- the brace position demonstration in case of an emergency occurrence
- the use of oxygen masks, and the importance of a passenger fitting his/her own mask before assisting others like children, disabled passengers, or others that require assistance
- the location and use of life vests, life rafts, and flotation devices in the event of an emergency landing occurring near a large body of water such as an ocean or sea,
- reminder of prohibition of smoking inside the plane, and more recently prohibition of any electronic smoking devices as well
- ensure mobile devices are switched off during take-off and landing (or kept to "flight mode")
- keeping seatbacks and tray tables upright and locked prior to takeoff and during landing, and stowing carry-on luggage inside the overhead locker or underneath a seat throughout the entire flight

As per Operation of Aircraft, Part I — International Commercial Air Transport, the ICAO has also set standards related to cabin safety, particularly to ensure international civil aviation sector provides cabin crew with sufficient trainings. The SARPs include the following (ICAO, 2018):

- The operator's in-flight procedures
- Passenger safety
- Carry-on baggage
- The minimum number of cabin crew required for each type of airplane
- The assignment of cabin crew members' emergency duties
- Cabin crew at emergency evacuation stations
- The protection of cabin crew during flight
- Cabin crew training programs
- Equipment required on board airplanes
- Cabin crew members' fatigue management
- Security-related procedures and security training programs (for the prevention of illicit acts against civil aviation)

In-flight Safety Videos Overview

With the increase of travelers in the commercial aviation industry, there has been an overall 7% increase in air travel in 2017 versus 2016 (IATA, 2017). Although the airline industry faces a low risk in terms of accidents, it is still highly susceptible to potential hazards that may occur due to pilots' inefficient decision-making skills or with the cabin crew's poor knowledge in dealing with an in-flight threatening situation (Molesworth & Wiggins, 2004). It is important to note that the low risk present in the aviation industry is associated with the regulations presented by the United States' FAA, and the Australian Civil

Aviation Safety Authority (CASA) (Tehrani & Molesworth, 2015). Moreover, aviation research findings revealed that online media streaming enhances the safety knowledge of crew members as opposed to traditional training methods (Bellazzini et al., 2008). This also implies that the easy accessibility of the material allows learners to re-watch air safety-training video and enhance knowledge retention (Bellazzini et al., 2008). Academic researchers attempted to compare the effectiveness of safety briefings in terms of card provided on the aircraft versus traditional in-flight videos versus in-flight videos that utilize more interactive technology (Chittaro, 2017). The findings show that there is no significant difference between in-flight videos incorporating interactive technology and traditional videos, but a significant difference compared to briefing cards (Chittaro, 2017). The results of the study raise the question as to why commercial airlines release less conventional in-flight safety videos.

It is crucial that any airplane that takes off must adhere to the regulations set by these government entities, which includes for any commercial airline to present its own in-flight safety briefing to all passengers on board. These requirements were stated in the earlier section. The aviation government entities have established a set of elements that is expected of commercial airlines to cover (Seneviratne & Molesworth, 2015). These aspects include providing the location of emergency exits, emergency lighting, demonstration of the brace position in case of an emergency occurrence, oxygen masks, location of life vests, and other reminders such as no battery operated gadgets, no smoking is permitted anywhere in the aircraft, and ensuring to keep mobile phones on flight mode during take-off/landing (Seneviratne & Molesworth, 2015).

Research findings from aviation journals suggest that paying attention to the in-flight safety video is a challenge to many passengers (Molesworth, 2014). Although the aviation government bodies such as FAA and CASA did not limit airlines' creativity in terms of in-flight safety delivery, most commercial airlines followed a dry, similar script (Molesworth, 2014). Commercial airlines face a greater challenge from frequent flyers, who already assume familiarity with the content, and therefore pays almost no attention to the safety information on board (Parker, 2006). A challenge stated by ICAO is FAA allowing all passengers to use portable electronic devices (PED) during the entire flight, except during take off and landing (Tang, 2013). This may suggest that when passengers are using their PED, they are less likely to pay attention to safety videos.

Traditional Factors in In-flight Safety Videos

Airlines need to ensure that apart from the regulated elements that need to be incorporated, there are several identified traditional factors that commercial airlines tend to tackle. The term traditional factors can be understood as factors that are expected and customary to any in-flight safety video. Similar to any video design and production team, these factors include the overall quality of the video in terms of its visual and audio aspects, video length (most safety videos range from 3 to 5 minutes in length), resolution, presence of subtitles, or clear voice-overs in other languages (Molesworth, 2014).

It is particularly important to ensure that consideration and provision are provided to passengers with needs and disabilities. To exemplify, for those passengers who may need to be accommodated due to hearing deficiency, airlines can incorporate sign language either in the video itself or appoint cabin crew to present the safety video as sign language. The recent trend that some commercial airlines started paying attention is how to successfully keep passengers engaged throughout the video. Premium airlines such as All Nippon Airways, Cathay Pacific, and Emirates Airlines, who had recently bagged the world's best airline inflight entertainment award (Rosen, 2017), still prefer a more traditional form of in-flight safety videos.

In addition, many organizations wanting to promote their brand name engage in brand name imprinting. This can be simply defined as displaying or exposing consumers with the brand name in a promotional aspect. Research confirms that imprinting brand name before presenting beneficial information facilitates consumers' ability to retain that information in their memory (Baker, 2003). This is particularly important for marketers who choose to only present the brand name at the end of a video.

Non-conventional Factors in In-flight Safety Videos

The Air New Zealand is considered a first mover in the game to revamp their in-flight videos. Other airlines then became fast followers, such as Cuba Pacific Airlines, and Qantas - they have moved away from what seemed to be a more conventional approach (Molesworth, 2014). Air New Zealand, as a leading airline to adapt an eye-popping approach, had not only achieved to gain passengers' attention, but also attract millions of views through viral marketing. Air New Zealand's Hobbit themed in-flight safety video have reached more than 18 million views in 2017 (Meltzer, 2017).

Commercial airlines have applied varying themes in an attempt to provide striking in-flight safety videos. Humor, celebrity involvement, or coinciding with a particular occasion are a few examples that airlines have successfully implemented in their in-flight safety videos (Molesworth, 2014). Research findings show that the economic value associated with celebrity endorsements reach up to \$10 million on an annual basis (Elberse & Verleun, 2012). Celebrity endorsements and involvement with brands is also found to positively enhance brand equity (Dwivedi, Johnson, & McDonald, 2015). A premium airline, Qatar Airways, decided to follow this path and release their in-flight safety video featuring football stars FC Barcelona creating another campaign that went viral (Platt, 2015). While this strategy certainly achieved gaining the attention of their passengers, it is unclear whether airlines do this for marketing purposes, or for the mere safety focus of passengers. However, it is important to consider the problem in the aviation sector: finding the optimal balance between flight safety and cost-effectiveness for the airline. The role of the ICAO comes into play as a way of harmonizing standards across the aviation sector to ensure safety is not compromised, while still remaining efficient (ICAO, 2016). The main advantage that viral marketing presents to airlines is that it does not require a large budget, but instead analyzing trends that create a buzz (Camarero & San José, 2011).

Another technique used by commercial airlines to overcome passengers' overfamiliarity and boredom, is the integration of humor (Molesworth, 2014). In a survey conducted to advertising agencies, results show that 90-92 percent of advertising experts confirmed humor as an effective tool to gain attention (Madden, 1984). Notable airlines such as Air New Zealand, Qantas and Virgin America have utilized this technique. Research findings show that passenger recall of safety information is more prominent in videos incorporating humor than celebrity endorsements (Seneviratne & Molesworth, 2015). On the other end, a comparative study found that participants' retention scores on safety instructions were the same for both humorous and non-humorous safety videos, which infer that passengers' safety may not be compromised by the use of humorous in-flight safety videos (Molesworth, 2014).

Other airlines prefer to promote the destinations that passengers can visit during their stay. The content of their in-flight safety videos revolves around tourist spots and breathtaking sceneries. Qantas and Singapore Airlines have effectively executed this technique. It also presents a more corporate image of the airline brand, compared to the use of humor or celebrities. Although it does reach a large number of views on social media platforms, approximately 300,000 to a million, it does not gain the viral marketing effect, unlike the use of pop culture and humor.

Numerous academic studies have explored online tailoring, or to simply put, adjusting the content of online information presented to varying individual characteristics such as demographics or gender. A recent study explored the use of online tailoring to understand its effects of attention and recall of online information between young and older adults (Nguyen et al., 2017). Findings show that tailoring information has a positive effect in information recall for older adults, but attention and recall for younger adults is the same for tailored or non-tailored online content (Nguyen et al., 2017). Air New Zealand was one of the airlines that have attempted this strategy by inviting celebrity comedian Betty White in their safety video (Air New Zealand, 2013, October 9). According to passengers, while some of the younger passengers did not fully relate, the rest of the older crowd definitely had a good laugh from the safety video.

Viral Marketing as a Strategy

Due to the success of airlines' non-conventional approach to in-flight safety videos, this has created a viral effect for many of their videos. A viral effect in marketing can be understood similar to virus that has rapidly spread across a large network through the sharing of a brand's information to both current or potential users (Dobele et al., 2007). After the proven success of in-flight safety videos that went viral, such as the Hobbit-themed safety video of Air New Zealand that gained millions of views throughout social media – although unsure of whether initially intentional or not, other airlines such as Qantas and Virgin airlines, have followed their fruitful path (Air New Zealand, 2014, October 22).

While the ICAO and federal regulators ensure that standardization is met across the aviation sector, there is a need for airlines to find the optimum balance between safety, management, and cost. The ICAO has set strategic objectives and Global Safety Aviation Plan (GASP) that is expected for airlines to achieve (ICAO, 2010). These objectives involve making sure staff is well-trained so that airlines are capable of responding to risk, conducting safety audit, and incorporating civil/military cooperation (ICAO, 2010). Commercial airlines can still comply with safety regulations, while adapting a less traditional marketing strategy, such as viral marketing.

Low cost and effective reach to mass audience are key conditions that make viral marketing as a strategy becomes very intriguingly attractive to many organization seeking to obtain effective communication channels to customers (Camarero & San José, 2011). Viral marketing utilizes technological communication through social media platforms to trigger the widespread of brand messages to a large network (Dobele, Toleman, & Beverland, 2005). To exemplify, airlines communicate their in-flight safety videos on social media platforms such as YouTube or Twitter that gain a wide reach of network. Hashtags are also used by airlines to enable social media users to quickly comment or share discussions on a particular thread, such as Emirates airlines' slogan, #HelloTomorrow or Air New Zealand's #AirNZMerryXmas during the holiday season.

Research findings have identified that successful viral marketing campaigns trigger an emotional response in recipients (Dobele et al., 2007). Results of a study suggest that in order for viral marketing to effectively take place, it is essential that the intended viral messages need to contain an element of surprise (Dobele et al., 2007). Additionally, it is not uncommon practice to recognize brands' efforts to tap social media platforms to introduce a new product or service. This is conducted hand-in-hand with viral marketing as a strategy. For example, researchers have discussed the strategy of the pop culture Britney Spears universe – how their aggressive attempt to promote a music video, with the objective to make it viral. In order to accomplish the viral effect, the video is discussed and posted on numerous

social media platforms such as Facebook, Twitter, and Youtube, to encourage and attract a large network of social media users (Kaplan & Haenlaine, 2012).

FOCUS OF THE ARTICLE

This chapter takes an exploratory approach, and primarily investigates numerous in-flight videos from various commercial airlines whose content is readily available on the YouTube platform. The systematic process searched for all airlines listed on Forbes' 2018 best airlines of the year list (Rosen, 2017). Each airline was then searched on YouTube for the last five years of in-flight safety briefings. These videos were then analyzed using a qualitative method known as content analysis (Bryman, 2008). Qualitative content analysis is a research methodology analyzing the content of messages, and translating it to meaning in the most objective manner (Bryman, 2008). The chapter also focuses and utilizes findings from literature reviews and news articles to interpret real-life secondary data. It is important to note that this is an exploratory study that focuses on elaboration of existing theory. The content analysis performed in this chapter mainly looks at the presence of non-traditional factors in the safety briefing videos of commercial airlines. In addition, it is also important to note that social media data is dynamic, therefore the results might not hold in the long run. This limitation can be addressed in future research studies by combining content analysis with descriptive statistics and trend analysis tool.

Although in-flight safety videos are discussed in academic literatures, there exists an underlying question as to whether airlines are jumping on the bandwagon producing entertaining content for marketing purposes or for passenger information retainment. This chapter then aims to fill the gap present in academic literature, and provide insights to the effectiveness of in-flight safety briefings, and explore whether premium or budget airlines present various strategies in the aviation industry.

SOLUTIONS AND RECOMMENDATIONS

Linking Airline Ratings to Presence of Non-conventional In-flight Safety Videos

This section of the chapter aims to shed light on the link between airline ratings and the utilization of non-conventional variables in in-flight safety videos. Table 1 presents a summary of the content analysis conducted of Forbes' 2018 best airlines against different elements that may or may not be present in in-flight safety videos. The five factors: traditional approach, utilization of celebrity or humor, promoting the destination, or accomplishing the viral effect. These key features were discussed in the background section of the chapter, and are important variables to consider in content analysis. As seen in Table 1, it is evident that the top best airlines have all boosted their in-flight safety videos using non-conventional factors to meet the innovative trends of recent years.

This may suggest a positive link between the use of less traditional factors and positive ratings of airlines. Another important observation is that top airlines, particularly, Air New Zealand and Virgin airlines, are not mere one-hit wonders. These airlines ensured to release more than one creative in-flight safety videos, addressing the struggle to keep passengers attentive, especially frequent flyers. Out of the list presented, Air New Zealand displays the most dedication by producing a total of 14 innovative in-flight safety videos since establishing the trend. This may create excitement and curiosity for pas-

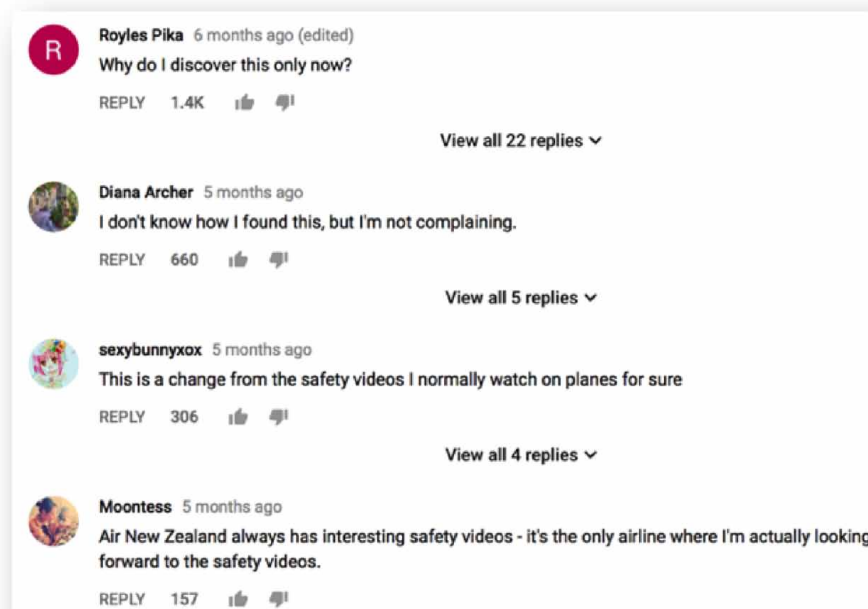

Table 1. Factors Considered by Airlines

Rank	Airline	Traditional	Celebrity	Humor	Destination	Viral Effect
1	Air New Zealand		x	x	x	x
2	Qantas		x		x	x
3	Singapore Airlines	x			x	
4	Virgin Australia		x		x	x
5	Virgin Atlantic			x		x
6	Etihad Airways	x		x		x
7	All Nippon Airways	x			x	
8	Korean Air	x				
9	Cathay Pacific	x				
10	Japan Airlines	x				

sengers about to board on their flight, and also maintaining passengers' attention before the in-flight safety video is played.

Through content analysis, it was also found that some airlines developed an entire campaign revolving around their in-flight safety videos. To exemplify, airlines such as Virgin and Air New Zealand promoted their hashtags in their in-flight safety videos published on social media platforms, such as #AirNZSafetyVideo (Air New Zealand, 2014, October 22). Evidence has shown that by doing so, airlines have started conversations around their videos on social media, by not only their passengers but also thousands of social media users. Figure 1 exemplifies social media users' excitement in not only the current in-flight safety video, but for the airline's future production as well. Therefore, it is safe to assume that if the user were to board the plane of the specific airline, he/she will most likely be paying close attention.

Figure 1.

Another important observation is the integration of the marketing campaign. Airlines from the top five of the list have incorporated elements of their in-flight safety video to other advertising campaigns. For example, Air New Zealand used the hobbit theme for additional areas of promotion, other than their in-flight safety video. This may portray the airlines' intention as to solidify their image to passengers, thus enhancing brand equity.

For the top rated airlines, it remains unclear whether the intention for the introduction of non-conventional factors was to eliminate boredom of passengers towards in-flight safety videos, or merely to promote their brand image through viral marketing. Nevertheless, the viral effect was achieved by most airlines, particularly due to the stimulating content triggering passengers' and other social media users' emotional connection, encouraging the exchange, likes, views, tweets, and comments on social media platforms (Dobele et al., 2007).

Due to the success received by airlines such as Air New Zealand, the added-value effect can be optimized from the enhancement of in-flight safety videos. Particularly when welcoming frequent travelers, it is essential that they still pay attention to the content and are engaged throughout, as it also enhances information recall in case of an emergency crisis. With this, marketing managers aiming to boost their brand value to customers and enhance customer-perceived brand equity can incorporate innovative ways to engage passengers during in-flight safety videos. Additionally, when recognized as an airline brand that is a dominant player in the creative side of inflight videos, airlines such as Virgin or Air New Zealand have proved to not simply be one-hit wonders. This has proven to encourage both frequent and new passengers to look forward to watching their in-flight safety video (Air New Zealand, 2014, October 22).

Airline marketing managers may also consider viral marketing as an effective strategy through the introduction of appealing hashtags, and integration of the overall brand promotion on numerous social media platforms to achieve a widespread interest from a large network of users. The network of social media users themselves create the viral effect through constant discussion, exchanges, and sharing in the social media community. This was also proven to be a low cost, yet successful to reach mass audience (Camarero & San José, 2011).

FUTURE RESEARCH DIRECTIONS

This chapter discusses a topic that is critical to airlines' implementation of successful in-flight safety videos. It also highlights its importance in airlines' potential marketing strategy. Numerous academic findings have suggested that passengers do not pay attention to in-flight safety videos due to boredom and overfamiliarity. With this, commercial airlines have integrated their in-flight safety videos with non-conventional factors such as humor and celebrities to address this issue. In addition, it is apparent that airlines have also attended to marketing opportunities that lie in safety videos. Air New Zealand, the airline rated number 1 according to Forbes 2018 list, was one of the first movers to capitalize on its in-flight safety videos. Their videos achieved a trend-setter status and phenomenal viral marketing effect with millions of views on social media platforms.

As discussed in the earlier section, an exploratory study was conducted. This is a limitation that will be addressed in future research by expanding the methodology from qualitative content analysis to descriptive statistics or trend analysis tools as form of mixed methodologies. In addition, for future research, it would be interesting to pursue a primary research, by conducting interviews to analyze passengers' perspective on airlines' in-flight safety videos. It would also be interesting to conduct a comparison between frequent flyers' perspective versus passengers who seldom travel. Passengers can be asked which

safety videos do they recall, and what factors should airlines consider when designing in-flight safety videos. Since it remains unclear as to whether non-conventional factors disrupt the recall of passenger safety information, this can also be tackled in a future primary research.

CONCLUSION

In-flight safety videos can be used as competitive advantage for airlines. There is certainly a trend for popular and successful airlines such as Air New Zealand to move towards less conventional forms of safety instructions. Numerous airlines have ventured onto creative means to capture passengers' attention, which is integral for surviving any critical emergency. It is also important to highlight that while creating creative methods to enrich passenger safety onboard, airlines are also able to capitalize on enhanced brand equity, and increased brand awareness through viral marketing with a wide audience through various social media platforms. While the main intention of previous airlines who have conducted successful in-flight safety campaigns remains unclear, other airlines can strategically attempt in-flight safety videos for the aforementioned benefits.

KEY TERMS AND DEFINITIONS

Brand Equity: The perception of value that consumers have about a brand name that is independent of the actual quality of the product or services.

Brand Name Imprinting: A marketing process or effort that businesses take in order to strengthen their brand in the market.

Commercial Aviation: The use of aircraft for hire by the public to transport passengers or goods.

Frequent Flyers: People who travels by air regularly.

Hashtag: A type of tag that is commonly used on social networks to allow people to search for a specific post.

In-Flight Safety: The safety of the passengers during flights.

In-Flight Safety Video: The required safety instructions in the form of a video that is played by an airline to the passengers before take-off.

Viral Marketing: A marketing strategy or gimmick that focuses on controversial topic or issue to encourage sharing of information by consumers.

Model/Anti-Model Advocacy Responses to Hospitality Industry Sexual Harassment

Jeffrey D. Brand

University of Northern Iowa, USA

Gayle M. Pohl

University of Northern Iowa, USA

INTRODUCTION

In 2006, Tarana Burke, an African-American civil rights activist, started a nonprofit organization, Just Be Inc. to aid survivors of sexual harassment and assault. She named the movement “me too” and began a campaign to help survivors, especially young women of color from poor communities to begin to heal from their experiences (Me Too, 2018). Actor Alyssa Milano used the #MeToo hashtag to promote the effort to recognize and give a voice to sexual harassment and abuse victims as the first accusations against Hollywood producer Harvey Weinstein were revealed across social media in 2017. That tweet quickly went viral and helped to launch the #MeToo campaign.

Since April 2017, other victims of sexual harassment and assault have spoken up around the country and the world to reveal their experiences and to expose their attackers. More than 263 people; including leaders and celebrities, in fields such as arts and entertainment, media, business, technology industries, politics, religion, education, hospitality services, and others; have been the subject to allegations of a variety of inappropriate and illegal activities including sexual harassment and assault (North, 2019).

These cases have revealed some challenges to effectively responding to these accusations. On the one hand, the individuals accused must be confronted and their specific behaviors and consequences identified and acted on. Many of those accused have been publicly shamed, their private lives and relationships damaged, others have lost their jobs, criminal and civil charges have been filed, and they have had careers and reputations ruined. At the same time, these cases have been held up as representative of larger problems in a variety of industries and institutions; including arts and entertainment, hospitality, media, business and technical organizations, politics and government, sports programs, and more. Identification and punishment of transgressors can only be a starting point for reforming the recurring and systemic conditions responsible for these actions. Transformations of organizational culture, institutions, and social expectations are necessary. Organizations have the opportunity to learn from these accusations and improve themselves and their industries.

The ongoing discourse surrounding the identities of people accused of harassment and other actions, along with efforts to address these issues within the organizations where these offenses have occurred, call for a scholarship that will extend beyond describing and categorizing accusations. Scholarship that should identify how this movement and its victims might see changes in the institutions and industries that created and allowed conditions for these behaviors to become “normalized.” Advocacy that is capable of transforming these institutions is necessary and can be identified in cases where accusers and institutions have made responsible efforts to change.

DOI: 10.4018/978-1-7998-3473-1.ch119

This chapter explores a case study in the hospitality industry by evaluating accusations against John Besh, a celebrity chef, and his organization, the Besh Restaurant Group (now BRG Hospitality). Applying the work of Perleman and Olbrechts-Tyteca (1969) and their identification of model and anti-model argumentation schemes, this study reveals how organizations and industries can address accusations against members (anti-model) and also propose and advocate for changes (model) to improve both symbolic and material conditions for their industry, their employees, and their stakeholder communities. Three objectives are established for this chapter. First, provide an evaluation of the discourses by leaders and members of the hospitality industry, celebrity chefs, and the mass media for their responses to sexual harassment and assault accusations. Second, reveal how the hospitality industry can employ model and anti-model arguments to advocate for changes in their industry and practices. Finally, identify the strategic purpose for using model and anti-model argumentation as an alternative to other reputational repair strategies for any organization facing accusations of wrongdoing.

BACKGROUND

Ulmer, Sellnow, and Seeger (2019), define an organizational crisis as “a specific, *unexpected*, and nonroutine event or series of events that create high levels of *uncertainty* and simultaneously present an organization with both *opportunities* and for threats to its *high-priority goals* (p. 7).” When individuals face accusations of harmful, inappropriate, and/or illegal behavior; their actions become the focus for judging their character, decision-making, and actions. When those same individuals are also in positions of power and influence; as celebrities, leaders, bosses, and other public roles of responsibility; the organizations and industries they lead and represent are impacted by their actions. Harmful actions by employees, leadership, and spokespersons can reflect back on the organization’s goals as well as the entire industry they represent. Tieying, Sengul, and Lester (2008) refer to these as a “spillover of negative impacts” created by crises that may impact their entire industries (p. 452).

Corporate America has a history of dealing with attacks to their image and reputation due to actions within and beyond their control. Many of the strategies are for responding focus on image restoration efforts to protect reputation. Benoit (1995) identified five image restoration strategies: denial, evading responsibility, reducing offensiveness of the event, corrective action, and mortification. Corrective action is seen as an effective response because “unlike compensation, which seeks to pay for a problem, corrective action seeks to prevent or correct it” (p. 45). Such a strategy of action and discourse is appropriate in a situation that encompasses organizational practices and corporate values.

The issues surrounding the #MeToo movement include values and beliefs related to organizational culture and social values that impact many stakeholders and industries. Organizations often serve as value advocates in addition to their central function as profit centers. To remain socially legitimate, organizations should represent and protect larger social purposes, and act in a “socially responsible and ethical manner” (Seeger, 1997, p. 9). Corporate and industry discourses may “seek to establish public frames of reference for interpreting information concerning issues deemed important.” As such, these efforts “not only reflect the society of which they are part, they also help create and recreate it” (Cheney & Dionisopoulos, 1989, p. 144).

Perelman and Olbrechts-Tyteca (1969) reveal that argumentation is capable of establishing a structure of reality by “resort to the particular case” (p. 350). By employing an argument from model and anti-model, an organization might choose to use their capacity to influence perceptions to restore credibility and support for their purposes. For example, Sellnow and Brand (2001) explored the effectiveness of

Nike's use of model argument to restructure public perceptions about their athletic shoe products in response to protests and boycotts in 1999. Brand (2007) also revealed how Merrill Lynch used model argumentation to restore investor confidence after civil and criminal accusations in its banking and investment divisions.

The public discourses surrounding the John Besh case and others that have been associated with the #MeToo movement, possess the potential to elevate discussions beyond attacking the individuals responsible for their actions and to make room for productive symbolic and actual organizational and cultural changes. Argument criticism has the capacity to advance the study of crises such as this one for the purpose of doing more than "understand any given reality. There is a need to transform it, to advance the cause of social protest, action, and change" (Denzin & Giardina, 2012, p. 18).

CHEF BESH, SEXUAL MISCONDUCT, AND HOSPITALITY INDUSTRY RESPONSES

In the midst of the swirl of accusations against celebrities, broadcasters, politicians, and other public figures in 2017, the results of an eight-month investigation by *The Times-Picayune* identified 25 current and former Besh Group employees who reported "that they were victims of sexual harassment while working at BRG or at a number of its restaurants" (Anderson, 2017, October 21). Accusations were directed towards John Besh, as well as his business partner Octavio Mantilla, and other members of the organization's management and leadership. Nine women agreed to have their names revealed in the report. Two women filed complaints with the federal Equal Employment Opportunity Commission (EEOC). Complaints and accusations in the article and the EEOC reports identified inappropriate touching, suggestive comments, efforts to coerce women for sex, and retaliatory actions for those who complained; as examples of conditions working for John Besh and in restaurants owned by the company. Additional federal discrimination complaints were filed against John Besh's restaurant group in December of 2017, echoing similar complaints found in the October investigative report and other EEOC filings (Anderson, 2017, December 28).

The accusations against Besh were not very different from the complaints filed against other targets of the #MeToo campaign; individuals with accusations from multiple victims with reports that supported and reflected repeated bad behaviors. The scope and number of complaints showed patterns of sexual harassment and assaults against women and have fueled the movement's efforts to address the larger issues that are revealed by these revelations. These accusations may be conceptually defined and categorized as efforts to: identify specific offensive and illegal actions on the part of John Besh and others targeted by victims of the #MeToo campaign; to reveal institutional and organizational norms and behaviors that have created the conditions leading to these offensive behaviors and actions; and finally, these accusations help to identify the characteristics of responses needed to address these crises.

The importance of the #MeToo movement and cases, like the John Besh accusations, is that they have helped to define and operationalize what accusers and victims mean by sexual harassment in the workplace. These accusations are conceptually difficult to understand until they are spelled out by the accusers and the frequency and similarity of the statements can be compared and compiled. Actions of physical and psychological abuse; work cultural norms and behaviors that reinforce these harmful conditions; the exercise of power and privilege over employees; and other revelations serve to create conditions that can allow scholarship to evaluate the adequacy and appropriateness of organizational responses and to recommend correction to existing organizational cultures and practices.

Application of Model and Anti-Model Argument

The use of model and anti-model argumentation presents a person or case to be either imitated or rejected based on its association to the values of the organization they reflect. Warnick and Kline (1992) explain that interest in “the model (antipathy for the anti-model) is converted into favorable or unfavorable orientation towards the model’s behavior” (p. 9). This argument scheme functions through use of a rhetorical process identified as dissociation, “whereby a unitary idea is bifurcated into two rival ideas” (Hearit, 1995, p. 121). Through dissociation, “one remodels the audience’s concept of reality and resolves incompatibilities (Schiappa, 1985, p. 10). Through dissociation, an organization or corporation can “claim that the wrongdoing is in no way reflective of how it generally does business” (Hearit, 1994, p. 121). Use of dissociation and model argument allows an organization to respond to a crisis and “regain its model status by shunning unacceptable practices. As such, an organization can reemerge as a model by stressing its unwillingness to conform to standards that are not acceptable” (Sellnow and Brand, 2001, p. 283).

As an academic practice, the evaluation of argumentation through model and anti-model argument reveals how organizations can define and represent themselves in situations where the actions or behaviors of the organizations are in opposition to their expressed values and mission. Arguments of this type conceptually identify the foundation of an organization and allows them to depict themselves as they advocate for an interpretation as aspiring to or meeting their objectives. To identify the application of model and anti-model discourses by organizations means to reveal what the organization accepts as model and anti-model performances by their members, leaders, or the organization as a whole.

Accusations of Sexual Misconduct against John Besh and his Organization

The case of John Besh, like that of Harvey Weinstein and the growing list of other accused harassers and abusers, is bigger than the accused. They represent abuses of power and authority that celebrities, owners, leaders, and public figures have wielded to harm women, minorities, and other vulnerable people. The accusations against John Besh and his associates in 2017 underscore the nature of complaints about powerful leaders, bosses, and celebrities and their treatment of others as part of the #MeToo movement. Consideration of their replies to these accusations should be assessed with not only the immediate context but the larger activity on the national stage.

The early responses by John Besh and his organization demonstrate an effort by the company to reply to some of the accusations without confirming the extent and seriousness of the investigative report by the media. At first, responses focused on ways to downplay the seriousness and scope of the accusations. John Besh offered that he had been in “consensual relationship with one member of my team” while married and that he is “entirely responsible for my moral failings. This is not the way the head of a company like ours should have acted, let alone a husband and father” (Anderson, 2017, October 26). In an earlier interview, Besh explained that he “would not characterize the values of this company in the way you just described” in the investigative report (Anderson, 2017, October 21). Besh later stepped down in his role as leader of the company and withdrew from visible management of the organization after publication of the investigation (Burton, 2017a).

Raymond Landry, general counsel for the Besh Restaurant Group, wrote that they “have learned recently that a number of women in our company feel that we have not had a clear mechanism in place to allow them to voice concerns about receiving the respect they deserve on the job” (Anderson, 2017, October 26). The 12-year old company, with multiple restaurants and more than 1,000 employees, did

not have a human resources department to process complaints or accusations until their first director started the job on October 11, 2017.

Business partner, Octovio Mantilla, argued that the accusations represented only a small number of the thousands of employees over the years who have not filed accusations, attempting to minimize the scope of the problem. The general counsel's statement also minimized the extent of the problem and made conciliatory gestures to show an appropriate response so that "the clear procedures that are now in place to safeguard against anyone feeling that his or her concerns will not be heard and addressed free from retaliation" will protect people who speak out against abuses in the future (Anderson, 2017, October 21). All of these statements represented the initial response to the investigations into the Besh Restaurant Group's treatment of employees.

The details of *The Times-Picayune* investigative report and responses by Besh added him to the list of persons accused of sexual misconduct that has been growing since 2017. Those complaints have formed the basis for new efforts to report and respond to sexual harassment allegations. *Time Magazine*, in the "Person of the Year 2017" edition, reported on the "Silence Breakers" who came forward to change "the way people view women who come forward" (Zacharek, et. al., 2017). Polls taken at that time also indicated that because of these cases women were more likely to speak out about harassment and be believed by other women (Zacharek, et.al., 2017). Although this accusation-making stage of the #MeToo movement has made progress in how people see the issues concerning treatment of women, minorities, and other vulnerable groups by persons in positions of power; further advancement is necessary. In another time, the initial responses by Besh and his organization might have been sufficient. The progress of the #MeToo movement, however, has generated the need for more extensive action and response.

After the initial revelations about the Besh Restaurant Group and John Besh stepped down, the organization restructured itself and announced the appointment of Shannon White as CEO. As the new CEO, White has been navigating the challenges of running the organization, even while Besh is reportedly still owner and having say over major business decisions concerning the company. Interviews and statements by members of the organization show the effort to design new model behaviors, policies, and procedures for the organization. In her initial letter to employees and members of the BRG team, new CEO Shannon White updated the members of initial plans to make institutional change happen. Included in her letter were statements about conducting an outside review and investigation, creation of an employee advisory committee, finalizing a sexual harassment policy and code of conduct, an employee assistance program, human resources training and education, among others. She committed the organization to be at "the forefront of a change in the hospitality industry and we will all be stronger and better on the other side" (Burton, 2017b).

By January, 2018, the parent company of John Besh's restaurants continued to advance changes. They changed their name from Besh Restaurant Group to BRG Hospitality (Carter, 2018). This was advertised as a way to recognize the new legal entity and coordination planned for the units in the company. They continue to work to adapt to the new reality concerning their businesses and finding ways to change their culture and industry. The organization, like many hospitality groups, has begun building the infrastructure necessary to develop a model of change and safety from past sexual harassment and assault issues. Changes including an employee hotline, new training, employee handbook, corporate code of conduct, employee advisory committee for feedback, an employee assistance program, and a complete internal investigation to identify other potential cases and problems not identified by the media's investigative report (Severson, 2018).

By adopting a strategy of model and anti-model advocacy, rather than just a reputational repair strategy, BGR Hospitality has moved to distance itself from the specific crises created by Chef Besh, and has sought to reform and transform its organization in ways it can to protect its employees, restaurants, and its future as an organization.

SOLUTIONS AND RECOMMENDATIONS

Expanding outward from the immediate leadership of BRG Hospitality, the discourses about the Besh accusations and restaurant culture start to take on new approaches and reforms. They became less about personal attacks and criticisms, and are more focused on the conditions that contributed to these cases and how to develop models for organizations and the industry to follow to avoid more of the specific anti-model behaviors reflected by chefs like John Besh and members of the hospitality industry.

In addition to the sexual harassment scandal surrounding John Besh, at least three other high-profile hospitality groups have been damaged by the sexual harassment and assault revelations and in the same vein of other #MeToo charges. Charlie Hallowell, in Oakland, California; Ken Friedman and Mario Batali in New York; have all been accused of sexual harassment and related charges, all have released apologies, and have been removed from daily operations or oversight for the restaurant groups they have helped create. As a whole, the restaurant industry has more sexual harassment claims filed against it than any other industry. Estimates as high as 90 percent of women and 70 percent of men are the victims of some form of harassment in their workplace by managers, coworkers, customers, and vendors (Reedy, 2019).

The actions advocated and taken by these hospitality organizations demonstrate the application of model argumentation that propose to alter the reality of their restaurants and the work environments to prevent and protect from the anti-model behaviors of their owners, founders and others. These cases reveal common problems that contributed to the conditions that led to work environments that employees have identified as reinforcing the anti-model conditions of sexual harassment and assault on employees. The advocacy efforts to correct these problems are proof of change and the expectation they will contribute to a new reality for the organization and industry.

One common variable for some restaurant groups facing these challenges is that they have not traditionally invested in human resource departments and management who could receive and listen to harassment complaints. Celeste Cooper, one of those reporting Charlie Hallowell for sexual harassment explained that without a mechanism to complain about behaviors they couldn't react. "I didn't think that it would be taken seriously, because he did that to everyone" (Duggan, 2017). BRG Hospitality, Charlie Hallowell's restaurant group, Ken Friedman's organization, and Batali & Bastianich Hospitality Groups have all announced changes in human resource areas; centralizing employee services and creating mechanisms for complaints and investigations (Severson, 2018; Duggan, 2017). In most cases, these organizations did not have centralized human resource resources or robust use of them. The restaurants often functioned independently without HR oversight. The absence of this type of corporate resource is generally considered problematic for larger organizations and even for small companies, the need for a human resources structure has become necessary in this industry in light of conditions that have led to sexual harassment and assault charges (Brasted, 2017). The addition of these changes presents one example in favor of a new model for the management of these organizations and a positive move for them. These new mechanisms do not address the specific charges against the celebrity chefs, but they do allow the organizations to dissociate themselves from past behaviors and indicate commitments to new conditions and treatments of workers to prevent the recurrence of past problems.

The restaurant groups who are related to the chefs accused of harassment and other misbehaviors have not only had to contend with changing their own internal structures and cultures, they have had to deal with the loss of partnerships and business opportunities that the accusations have endangered. Harrah's Casino in New Orleans dropped the Besh name from its restaurant Besh Steak after the accusations went public, attempting to distance themselves from the public perceptions of the culture of the restaurants owned or managed by the Besh Restaurant group. The South Beach Wine & Food Festival had promoted a dinner event co-hosted with John Besh who was then replaced with Amanda Freitag, a judge on the Food Network's *Chopped* show. (Carter, 2017). Other business ventures have also been cancelled or held up.

Mario Batali's organization, B&B Hospitality Group, announced that three of its Las Vegas restaurants would close on July 27, 2018. The partner in those businesses, Las Vegas Sands Corp., chose to end its relationship with B&B and close all three properties. These announcements came shortly after a *60 Minutes* report expanding on accusations against Batali for sexual harassment and assault (Mancini, 2018). Batali was the subject of investigations concerning sexual assault in two states, New York and Massachusetts. The investigations in New York were closed when the police could not find enough evidence for an arrest (Southall and Moskin, 2019, January 8). Although he was reported to have been exploring ways to making a comeback in the business in April 2018, plans to divest him from his restaurants continues with B&B Hospitality (Plagianos, 2018). Other business relationships have also been revised or altered since the accusations were made public against the chef.

Like other professions and industries faced with the accusations of sexual harassment and assaults, the restaurant industry's leadership and membership are called to reply to this situation and to reinforce proposed changes that may help alter perceptions of its culture. The late Anthony Bourdain, who was also supportive of other victims in the #MeToo movement, tweeted in response to the report on John Besh, "The beginning of the end of institutionalized Meathead Culture in the restaurant business" (Rainey 2017). Chef Jose Andres in Manhattan, NY also responded, "Need to make sure Restaurant industry is actively leading the way, respect, dignity, humanity is non negotiable. Specially protecting women" (Rainey, 2017). Although some chefs, restaurant owners, food journalists did speak against Besh as an anti-model of behavior and standards, the immediate reaction was not deafening. This point was made by restaurant owner and author Jen Agg who commented, "It's worth noting FAR MORE journalists and non restaurant people seem to be talking about Besh than the restaurant people who should be" (Rainey, 2017).

Celebrity chefs who have been accused of sexual harassment and assaults also experienced backlash from colleagues. As this cascade of cases including Besh, Batali, Friedman, and others have played out; other chefs have replied with their concerns about their industry and how male chefs are going to need to change their behaviors. Chef Tom Colicchio, in an open letter to chefs and the restaurant industry, wrote candidly about the need to reform the culture and expectations that have led to these abusive conditions. "I'm betting we can reinvent our industry as a place where people of all genders feel safe and prepared to lead" (Colicchio, 2017). Colicchio's letter was not only an attack on a culture that has contributed to the current crisis, but also one that has made it difficult to advance women and minorities within the industry as a whole and has endangered the success of the restaurant industry overall. "Can we finally redefine, in our collective minds' eye, what the race, gender or sexual identity of a top chef might be, and take the steps to make that happen?" (Colicchio, 2017). Colicchio's letter came at a time when the restaurant industry and chef culture is facing multiple challenges, and these harassment cases have only made it more difficult for the industry to thrive. At the same time that working conditions for women and minorities are being challenged; low unemployment, the crackdown on illegal immigration, and

alternative choices for cooks and chefs beyond traditional restaurants are leading to shortages and staffing problems for the industry (Maynard, 2017, November 10). Colicchio's advocacy for change reflects his support for reforms broadly, "It's going on everywhere. It's pretty clear that this isn't an issue for just the restaurant industry. It's a problem with our culture" (Andrews, 2017).

Model and anti-model arguments within the industry and from related groups and organizations are contributing to the voices advocating for a renewed industry that can address its challenges; not simply attack those who have abused others and have damaged the reputation of the industry. After the accusations against Chef Besh were revealed, a number of television cooking shows and networks cut his ties to him and cancelled appearances and shows, even reruns. PBS station WYES announced that it would no longer air productions featuring Besh, explaining that "WYES would not want any viewers to think that broadcast of those programs represented condonation of actions of the type alleged" (Sayer, 2017). Broadcast outlets represent an important revenue stream for celebrity chefs, but they are sensitive to allegations of sexual harassment and other inappropriate behaviors. Public television stations have a code of integrity that influences not only what is shown on their channels but also the behaviors of those hired to produce content. One example of the code states they "Expect employees to uphold public media's integrity in their personal as well as their professional lives, understanding that employee actions, even when 'off the clock,' affect trust, integrity, credibility and impartiality" (Maynard, 2017, October 24). A Bravo network show edited John Besh out of an episode of "Top Chef," a show he had guest judged on for years (Andrews, 2017). Other food related programs have also removed, delayed, or cancelled productions associated with celebrity chefs accused of harassment. Mario Batali was asked to leave co-host role in the ABC series "The Chew," and a planned production of a revival of his "Molto Mario" show for the Food Network has also been placed "on hold" (Bartiromo, 2017).

Restaurants and chefs have benefitted from the publicity that television has given them, and for expanding the celebrity culture of many chefs and restaurants. As such, their voices and production decisions are now capable of reinforcing change and models of industry behavior that should not negatively harm their financial interests. The harassment charges against Besh and other celebrity chefs continues to spill over into other businesses and the public's perception of them. Reactions by broadcasters and others also utilizing model and anti-model discourses are also helping to advance transformation in their organizations or risk losing their standing and opportunities in business.

The restaurant industry recognizes its best through a variety of awards, rankings, and honors. The Beard Foundation's, James Beard Awards, are one of the highest honors for a chef to receive. The award confers a level of excellence that leads to greater financial and social recognitions for its recipients. Many of the celebrity chefs accused of harassment and assault have been past winners of the award. Besh was a two-time winner and a Who's Who inductee. Batali won five Beard awards, Ken Friedman won the Outstanding Restaurateur award in 2016 (Canavan, 2017). In its instructions to judges for 2018 it asked judges to incorporate issues of behavior including these allegations and others in their nominations criteria. "The Restaurant & Chef awards honor professionals who serve as industry leaders. More than ever, we are thinking about respect and integrity when making recommendations for the semifinalists. As judges we ask you to do the same." (Canavan, 2018). The Beard Foundation, like other organizations working within the restaurant industry has been understandably impacted by the actions of their celebrity award winners. As such, their arguments and responses to this crisis count and have the power to influence public perceptions and the industry's pathway to changing its behaviors.

The overall impact of the accusations against John Besh and his organization have extended well past it into the restaurant industry as a whole. The profession and organizations that participate in this indus-

try have begun to identify its best and worst practices, established a dialogue and ways to communicate about them, and as a result recommend changes in their organizational culture, practices, and leadership.

FUTURE RESEARCH DIRECTIONS

The growing wave of accusations and accounts of sexual harassment, assault, and abuse, revealed in the wake of the #MeToo movement and by other victims, are themselves worthy of documentation, discussion, understanding, and outrage. The recording of these events and identification of these behaviors is a necessary step that have revealed hundreds of celebrities, public figures, and leaders for their harmful behaviors towards women and other vulnerable persons. These cases are also likely to reveal more as well as complaints against many others in their industries regardless of fame or celebrity. This study of accusations against John Besh and the further cycles of discourses about chef culture and actions by other members of the hospitality industry has demonstrated that the evolution of this movement must go beyond shaming, out casting, labeling, and accusing its unworthy role models and leaders. Academic scholarship, applying an understanding of argument schemes like model and anti-model argument, should participate in “giving people a language and a set of pedagogical practices that endeavors to turn oppression into freedom, despair into hope, hatred into love, doubt into trust” (Denzin & Giardina, 2012, p. 21). The advocacy approach represented in model and anti-model argument suggests rich potential for further research to advance understanding the #MeToo movement and other industry-wide crises that address sexual harassment cases and other industry challenges.

The argument schemes identified by Perelman and Olbrechts-Tyteca represent “distinct, culturally-held beliefs about the ways we form new beliefs from already accepted premises” (Warnick and Kline, 1992, p. 3). Model and anti-model argument schemes have the potential to shape the “structure of reality” understood by the audience to create “new audience perceptions” (Warnick and Kline, 1992, p. 3). Like Denzin and Giardina’s (2012) call for a scholarship that transforms society, the application of the model and anti-model scheme represents a rhetorical strategy that establishes in “the realm of conduct, particular behavior may serve, not only to establish or illustrate a general rule, but also to incite to an action inspired by it” (Perelman and Olbrechts-Tyteca, 1969, p. 362). Further research to explore the discursive power represented by model and anti-model argument may be able to not only identify its application but also successes in transforming the members of an organization in significant ways.

Finally, this chapter has helped to define and explain the concept of model and anti-model argument and to apply it to organizations and industries that need to do more than just repair their reputation or image. This research program allows for the consideration of efforts to effectively communicate during a crises and to move beyond the moment to enact change and transformation. Although research into reputational repair and organizational learning has frequently focused on repairing the public’s attitudes towards an embattled person or organization, this research represents an opportunity for additional consideration of strategies that seek to transform and change organizations, to help them learn to adopt new values and behaviors appropriate to their mission and public perceptions of their role in society.

CONCLUSION

This chapter has established the importance of evaluating the chef John Besh accusations, and those of others in the hospitality industry, by exploring model and anti-model arguments used to define and respond

to the controversies revealed and amplified by the #MeToo movement. They extend beyond any single industry or organization to the larger cultural system that has contributed to sexual harassment and abuse by those persons of power and authority. Viewing these accusations in this manner has demonstrated that the perceptions of reality and the capacity to guide and change those beliefs and actions can begin, only if a discourse that demonstrates the alternative model to current anti-model behavior can take place.

The hospitality groups once led by the accused, other partner organizations, celebrity chefs, industry associations and representatives, all have employed a rhetoric of model and anti-model argumentation that creates conditions to limit and isolate the actions of some of its membership from the rest of the industry. They are using “the act/essence dissociation to claim that the wrongdoing is in no way reflective of how it generally does business” (Hearit, 1995, p. 121). These acts of corporate and organizational discourses demonstrate that “public relations statements and issue management campaigns not only reflect the society of which they are part, they also help create and recreate it” (Cheney and Dionisopoulos, 1989, p. 144).

Although the #MeToo movement and initial advocacy concerning it is relatively new, this chapter has explored how revealing the harmful, anti-model values and actions in the hospitality industry might be a step towards reform if the counterweight of model argument is offered, and the expectation for transformations of perception, behavior, and action take place. As such, this chapter provides a method for organizational change and learning for a variety of industries. A strategy rooted in model and anti-model argument and advocacy can assist an organization to respond effectively to a crisis; to dissociate the crisis from the rest of the organization; and to recommend the changes necessary to transform the organization from a position of failure to uphold expected values and behaviors to one where the organization can now succeed and become a role model for its stakeholders and community.

KEY TERMS AND DEFINITIONS

#MeToo Movement: A movement responsible for revealing sexual harassment and abuses against women and other disadvantaged individuals by persons in power and influence. The movement has advocated for change in many industries and fields, both in the United States and worldwide.

Anti-Model Argument: An argument identifying unacceptable behavior or messages the advocate wishes to discuss.

Dissociation: An argumentation process that separates one set of actions or behaviors from another.

Hospitality Industry: An industry encompassing food and drink venues, entertainment sources, travel and tourism, lodging and recreation services.

John Besh: A celebrity chef and restaurateur accused of inappropriate sexual harassment and abuses by employees.

Model Argument: An argument identifying the accepted behavior or messages that the advocate wishes to promote.

Organizational Crisis: Any event that threatens an organization's reputation or credibility due to actions by employees or leadership of the organization.

Section 11

Knowledge Management

Useful Organizational Knowledge via Knowledge Elicitation and Management

Ronald John Lofaro

Embry-Riddle Aeronautical University, USA

INTRODUCTION

Currently, and with almost light speed, new advances in both human-centered and technology-driven efforts have led to new methods in obtaining and using organizational knowledge. For the purposes of this Chapter, Organizational Knowledge will be seen as the different knowledge and skill sets that the employees of a large company or organization have, and how these can be used and shared to make the organization more effective. The emphasis will be on how to elicit those knowledges and how to evaluate their usage. As examples, Organizational Knowledge can be used in analyses of the structure, techniques and functioning of an organization. Organizational Knowledge can also play in identifying the areas where research is needed, what new knowledge is needed for possible re-organization...and be part of any decision-making that impacts the organization. The author's goal is to explicate a new model for eliciting and using Organizational Knowledge. This Chapter will build a model composed of both old techniques and technological advances in human knowledge elicitation, then using and evaluating the human knowledge gained, plus elements of knowledge management and Pareto analysis. This new paradigm uses all of the components above in a blended Delphi. Advantages of using the components listed are that they are all content-area neutral and, in a real sense, generic in application.

BACKGROUND

The Delphi method was developed by the now USAF's Project RAND during the 1950-1960s. and derived its name from a contraction of the term research and development (**R**esearch **A**nd **D**evelopment). The Delphi technique has long been used for eliciting knowledge from subject matter experts (SMEs) and has become a common methodology/methodologies for eliciting analyses, expert opinions and evaluations on a variety of topics. Delphi techniques, a subset of CE/KE, have a goal at arriving at something closer to expert consensus. The Delphi method has been widely adapted to work problems and is still in use today. It has changed over the years from SME anonymity to allowing face-to-face groups (estimate-talk-estimate; ETE) of SMEs. Meister (1985) noted "The (Delphi) methodology is by no means fixed...[it] is still evolving and being researched." This is as true now as it was when Meister stated it. In point of fact, with the leaps in communication methods and related computer technology, this is even more true today as Delphi techniques have recently begun to look at and attempt to take full advantage of these advances.

One also finds that an expansion in the the field called cognitive/knowledge engineering (CE/KE) has occurred and is still in progress. KE was defined in 1983 by Edward Feigenbaum and Pamela McCorduck as follows: "KE is an engineering discipline that involves integrating knowledge into computer systems in order to solve complex problems normally requiring a high level of human expertise." For a

DOI: 10.4018/978-1-7998-3473-1.ch120

more complete overview and discussion on KE, differing views and uses, the reader is referred to Studer, Benjamins and Fensel (1998).

There is a new emphasis on a related discipline: knowledge management (KM). The field of KE has recently expanded to encompass KM as a subset. KM has been defined as “...the practice of selectively applying knowledge from previous experiences....with the express purpose of improving the organization’s effectiveness.” (Jannex, 2014). For works on KM, Amazon’s web site has 50 or more, including the ubiquitous *The Complete Idiot’s Guide to Knowledge Management* (Rumizen, 2001).

Pareto Analysis has a long history of being used processes to focus on selecting the best course of action for dealing with issues/problems. Pareto analysis is a formal technique useful where many courses of action are possible. In essence, an estimate or criticality rating is done that allows for selection of effective action (s) that deliver a total benefit to an organization or other entity. Pareto analysis is a creative way of looking at causes/”cures” of organizational problems as it helps stimulate thinking and organize thoughts

The newest sub-set/direction of knowledge elicitation and management is knowledge management success, KMS. KMS is “...a multidimensional concept defined by capturing the right knowledge, getting the right knowledge to the right user and using this knowledge to improve organizational and/or individual performance...” (Jennex, 2012 citing himself, Smolinik and Croasdell, 2009). Thus, KMS evaluates the success of the processes and knowledge generated as the organization develops and uses knowledge about itself. KMS today places emphasis on the success of using a KM process in organization-wide endeavors.

Collectively, all of the above could be used in a paradigm for developing organizational knowledge for such processes as decision-making, reorganizations and future research needed, all on an organizational level

The author is here attempting to show how a Small Group Delphi Paradigm (SGDP)/Estimate-Talk-Estimate (ETE) amalgam with a modified Real Time Delphi (RTD) could be used on some specific problems, as well as adding in the use of a mini-Pareto as a start point. And, evaluated as KMS. Finally, this Chapter will outline a blueprint/framework for the processes for using this new paradigm, in real time. All being done in the hopes that such efforts might be of some interest to current and future researchers in developing, using and evaluating Organizational Knowledge. This Chapter will begin with the development of the Small Group Delphi Paradigm, SGDP (Lofaro, R.J. 1992) in 1985/6.

The Small Group Delphi Paradigm: Origin

As the SGDP lies at the heart of the model to be explicated, we begin here. However, space requirements preclude all but a bare bones treatment. For a much more complete exposition, please email the author; lofaro@msn.com.

The SGDP was somewhat controversial yet was actually the first iteration of the now accepted ECE Delphi. It began with a specific problem and task: to develop for the U.S. Army Aviation Command an computerized aviator candidate selection test that also showed which of the current rotorcraft would be the optimum operational aircraft placement for the candidate upon completion of initial training. In short, Army Aviation wanted to initially train pilots **and** immediately afterward put them in transition training for one of then then operational rotorcraft, based solely on a test. Historically, there were several articles that voiced strong objections to a Delphi not being anonymous. A major one being that having participants see and interact with each other would at best, dilute results, and at worst, negate them. As an example, Pill (1970) had said that this may dilute the opinions of the real expert. These the objections seemed to the author to be somewhat bizarre. First, the subject matter experts (SMEs) selected ARE the

real experts. Not only that, the reality (based on the author's having conducted several workshops using SME's to focus on and solve problems) was this: The other SMEs recognize, welcome and use another SME's expertise—as their goal is the best result/product possible.

Another objection was that the group dynamics may force ratings and analyses towards a mean or middle ground that does not fully reflect all the SMEs' views. In response, true SMEs will not allow that to happen for personal reasons and pride. They will not “go along to get along.”

The instruction in group dynamics and group processes, the trained facilitator and the iterative methodology to be used were designed to ensure such prior objections could be met. The objections to a new, face-to-face Delphi could not only be overcome but the use of group dynamics coupled with traditional Delphi processes could add robustness and a completeness, as it were, to results obtained from this coupling. In this new Delphi process, the abilities approach of Fleishmann was used. In their book, *Taxonomies of Human Performance*, Fleishmann and Quaintance (1984, revised 2000) state that “specific tasks are said to require certain ability profiles if performance is to be maximized. Abilities provide a natural basis for describing and classifying tasks in terms of human performance requirements.” Fleishmann and Quaintance defined ability as “an innate enduring attribute.” As such, abilities are indicators and predictors of later skill development. Put another way, the ability requirements theory/approach is away of describing and classifying human tasks. Once a set of tasks is identified, a human performance taxonomy can be developed from it. Taxonomy, as used here, denotes a system that classifies and describes human tasks according to a particular focus, such as the abilities seen as essential to specific task performance.

The process used in 1985/6 was face-to-face, small groups (five and ten) of Army aviators, who were recognized by their peers as exceptional pilots in their particular rotorcraft from all Army posts worldwide, functioning as SME's. These SME's were given a 30 page read-ahead package. After some weeks, these SME's were brought to Ft. Rucker where they would have group function/dynamics training, and begin facilitated group work to achieve consensus on the objectives specified in the read-ahead. This endeavor came to be called the small group Delphi paradigm (SGDP). Thus, the SGDP took the Delphi process in another direction by modifying it via merger with elements of group dynamics in order to have interactive (face-to-face) Delphi workshops. These modifications resulted in a paradigm for using small groups of subject matter experts (SMEs) in a workshop setting.

The basic categories the author and associates looked at in the original 1986 SGDP were psychomotor (hand/eye coordination as an example); cognitive; personality characteristics. Thus, we were establishing what would be called today an ontological scheme to reduce complexity and structure the data. A KE/KM ontology compartmentalizes the variables needed for some set of computations and establishes the relationships between them; thus, an ontology is used to limit complexity and to organize and structure information. After the SME's identified the skill sets this completed the ontological taxonomy for each helicopter. Sub-tests were then chosen (or modified from existing ones) to provide measures on skill sets found in the workshops. Finally, a unified test and scoring algorithms were developed. The use of multivariate discriminant analyses resulted in a “profile” of the (weighted) factors that made for success for pilots, but in only three of the four rotorcraft. It was found that that each centroid contained the same set of what we called basic rotorcraft piloting skills, common across all centroids and second sets of skills, particular to only one rotorcraft. It was determined that this common set of skills were those needed to pilot the UH-1 Iroquois (called the “Huey”), at that time the basic Army operational rotorcraft. This finding was both vital and important. It showed what we had thought and what, informally, the SME's had brought up: there was a set of basic pilot skills needed for all rotorcraft. This also boded well for the selection aspect of the test. Secondly, each rotorcraft has a secondary set of skills specific

to that rotorcraft; this boded well for the placement aspect of the test. And a real serendipity: when the Army was going to go over to new training system, they were going to stop using the then initial training rotorcraft, the TH-55, a piston-engined relic. The UH-1, which was as were all Army operational rotorcraft, jet engined, was to now be the initial training rotorcraft. The skills common across all three centroids were extracted and formed a fourth centroid; the UH-1 skill set centroid.

Thereupon, The U.S. Army Aviation Center made the test battery and set of algorithms (now called Multitrack, as was the new training system) operational. It was successfully used in selecting rotorcraft aviator candidates for initial rotorcraft training and later, placement in their operational rotorcraft for more than five years

At this point we must mention validity. The original concern was neither with internal nor with external validity. i.e., if the results of a study are generalizable or transferable...most discussions of external validity focus solely on generalizability (Campbell and Stanley, 1966.). [Aside: However, our work was both generalizable **and** transferable]. The researchers' main concern in 1986 was with predictive validity: the degree to which the test battery can predict (or correlate with) with success of the construct in operational use. Of import are both the high "pass" (success) rate when the pilots were placed for transition training in the operational rotorcraft Multitrack indicated versus the high "fail" rates when, for some bureaucratic reason, the pilots were not placed in the optimum first choice or even the second choice rotorcraft. In sum, The SGDP accomplished what had never been done before. It delivered an operational, computerized set of tests with scoring algorithms that not only selected the best aviator candidates for initial pilot training but also showed which of the four then-existing rotorcraft types these candidates should be placed for transition training upon completion of initial training.

NOTE: Complete statistics on the extremely high predictive validity are available (Lofaro, Intano & House, 1990). This initial SGDP R&D effort has been extensively presented (Intano, Howse & Lofaro, 1991; Intano & Lofaro, 1990; Intano & Lofaro, 1989; Lofaro & Intano, 1989).

The Small Group Delphi Paradigm: Past Uses

In 1986, the author did not realize the potential of the SGDP in other venues, areas, problems. But, from 1987 through 2003, the SGDP was adapted and successfully used in a broad spectrum of tasks. In 1987-1988, the SGDP was used to develop a training syllabus to achieve an optimum performance level; In a Federal Aviation Administration-sponsored project that developed a computerized air traffic control specialist (ATCS) selection test battery (Gibb and Lofaro, 1993); in identifying airline baggage x-ray screener abilities and developing a prototype test for both selection and evaluation of aircarrier baggage screeners (Lofaro, Gibb and Garland, 1994; Gibb and Lofaro, 1994) [Note: In this endeavor, Lofaro gave training to Gibb and associates in doing the SGDP as he was not able to facilitate the Delphi's himself. Lofaro also provided Gibb with a written precise of the SGDP technique. Gibb and associates did the actual SGDP workshops themselves at various locations. The successful use of SGDP techniques by others indicate that the techniques are not dependent on who administers them; rather, they not only are effective across venues but also with different personnel directing/facilitating the SGDP workshops.] To resume: The SGDP was used in developing sets of specific managerial and employee core competencies (Lofaro, 1998, 1999) and lastly from selection through to useability testing (Lofaro & Maliko-Abraham, 2002; Maliko-Abraham & Lofaro, 2001, 2003).

In Sum: As said above, these successful adaptations, modifications, implementations, across many venues, showed that the SGDP is both transferable and generalizable.

The SGDP: Technological Innovations

Some twenty-five years after the SGDP was devised, used and appeared in multiple publications, it has been re-discovered, as it were, and is now recognized as an acceptable Knowledge Elicitation method. The use of face-to-face groups in a Delphi is now a fact and is termed Estimate-Talk-Estimate (ETE). New communication capabilities and technologies seem to have driven the development of what are generically referred to as a mini-Delphi or ETE, with many variants. There is also the Real Time Delphi (RTD) that maintains anonymity but uses computer linking for a high level of instantaneity (Gordon, T. J., & Pease, A., 2006). While the SGDP structure and processes are still relevant, they can be and are in real need of some level of integration with ETE/RTD techniques and current advances in computer and communication abilities and techniques. The author's belief is that the result of an integration would be a revised Delphi that will produce the same level, if not a higher level, of accurate information in many venues. In modifying the SGDP for use with today's technology and advances in KE/KM, any problems to be investigated would require, as a first step, the building a model of a knowledge domain, defining the terms inside that domain and the relationships among them...developing an ontology. We will return to this later.

A MODEL OF A BLENDED SGDP/ETE/RTD

Before we look at expanding the SGDP to bring it into today's era, let us state the core components of the SGDP, the ones that must be at the heart of all new work with it. Again, for a more complete SGDP write-up, email the author; lofaro@msn.com. The core SGDP structures to be maintained are: the careful selection of a limited number of SMEs (however, there can be many small(er) SME groups functioning at one time); the preparation of an extensive and comprehensive set of SGDP objectives; the use of an explanatory read-ahead package for the SGDP members, one which contains the objectives and the use of group dynamics and finally, before the initiation of the SGDP, the use of some facilitation and group dynamics instruction in face-to-face sessions. On to the blended model. One example of a difference in an ETE or RTD (a computer-based Delphi with anonymity) versus either a traditional or SGDP Delphi: the iteration structure used in the traditional or SGDP Delphi, which is divided into three or more discrete rounds, can be replaced by a process of continuous (roundless) interaction, enabling SMEs to change their evaluations at any time. A new ETE/RTD/SGDP model would be computer-based. The reader is referred to the work of Turoff and Hiltz (1996) on computer-based Delphis.

Integration of the SGDP with a ETE/RTD (*sans* anonymity) approach can be achieved thusly: all participants can be logged on simultaneously, each participant can briefly state their name and credentials, the group dynamics instruction can be done by the facilitator to all simultaneously (aside: it would seem that a linked network of all SMEs is possible and even *de rigueur*). The SGDP face-to-face group meetings would now be done on-line. This will allow for instantaneous feedback by any SME during a session, as well as discussions). The iteration structure used in SGDP, which is divided into as many discrete rounds as needed for consensus, can be replaced by a process of continuous (roundless) on-line interaction, enabling SMEs to change their evaluations at any time and give a rationale with ensuing discussion in real-time. Finally, the statistical group(s) response(s) can be updated in real-time and shown whenever a SME, or a group, provides a new evaluation. It is clear that "face-to-face" discussion will be virtual. This is, to the author, a real and significant loss. But, the speed, multiple iterations, real-time, access to a large number of SMEs and other aspects to be gained cannot be ignored. Another possible modification

is a multi-tiered SGDP/ETE/RTD where the use of two or more groups working different problems can be convened and given objectives based on their expertise. As these groups come to consensus on their objectives, these new data can be integrated, built into a new re-ahead package and made available to a new set of participants with new or prior SME's.

A second modification would be use of only specific elements of a Pareto Analysis as the first step after the group dynamics instruction. This is because such a step would identify problems, then, sharpen (focus in on the ones that are amenable to resolution) while, at the same time, providing an ordering of which should be worked on via criticality ratings. The elements of the Pareto Analysis would be the first three steps in such an analytic technique. Step 1: Identify and list problems to be examined. Or, if and only if one problem/issue exists, a break-out of the sub-problems could be done. Step 2: identify causal factors inherent in each problem. Step 3: Score (in this case, criticality rate) the problems, resulting is a somewhat rough ontology. The Pareto, done in the context of a SGDP/ETE/RTD could also allow for many possible solutions to be evaluated by many types of SMEs with differing areas of expertise but in areas germane to the problem. This would result in a winnowing down of courses of action to those that were realistic and possible of success. The advantages of using a Pareto, core SGDP structure and ETE/RTD (all computer/Internet driven) are that they are all content-area neutral and, in a real sense, generic in application.

A SPECIFIC EXAMPLE OF POSSIBLE PARADIGM USE

This paper will only deal with one current commercial aviation issue. The author's 26 years of experience in aviation; United States Air Force, Army Aviation Command, and the Federal Aviation Administration (FAA), simplified that choice. There is a significant amount of controversy over upset training; training pilots to recover the airplane from unusual (unstable; dangerous; rarely encountered) attitudes thereby not having potentially fatal accidents. The Air France Flight 447 accident, for example: A series of errors by pilots and a failure to react effectively led to the crash of Flight 447. The plane went into a sustained stall, signaled by a warning message and strong buffeting of the aircraft. Despite these persistent symptoms, the crew never understood they were in a stall situation and, therefore, never undertook correct recovery maneuvers. In other words, a high altitude, high speed stall was a situation the crew was unable to recognize much less had ever trained for. The Colgan Air crash outside of Buffalo, NY is another fatal accident where the U.S. National Transportation Safety Board (NTSB) determined that the probable cause of this accident was the Captain's inappropriate response to the activation of the stick "shaker" (the airplane's main control device actually shakes/vibrates in the pilot's hand if the plane is in danger of stalling/spinning) which led to an aerodynamic stall from which the airplane did not recover. To further cloud the issue, the American Airlines upset prevention and recovery training (UPRT) ground school with flight simulator (FS) training, called advance aircraft maneuvering program (AAMP), was seen by the NTSB as possibly a contributing factor in the American Airlines flight 587 crash in 2001 (Croft, John. 2014a). The FAA, while not yet issuing an Advisory Circular or a Federal Aviation Regulation issued a document called Airline Upset Recovery Training Aid, version 2. The current issues seem to be use of a full motion FS, that will be part of an expected FAA pilot training rule by 2018 (Croft, John. 2014b), versus in-aircraft training (or some combination) and swept wing jet aircraft specialized training. It is believed that a modified SGDP/ETE/RTD, using senior pilots as SME's can point a way to types/procedures and applicability for upset training.

This SGDP/ECE/RTD would proceed thusly: A multi-tiered effort, beginning with the Pareto described above to identify 2 or 3 issues that most need solutions (a quasi-ontology) from the issues cited above: use of a full motion FS and/or in-aircraft training and/or swept wing jet aircraft specialized training. Next, as always, multi-tiered, identify the sub-issues involved. Here, as with the remainder of the SGDP/ETE/RTD, the data needed for all tiers/sub-tiers would come from SGDP/ETE/RTD's consisting of 5 to 9 (senior) pilots from as many aircarriers as possible. Possibly, each interested carrier initially could do such efforts. In this way, each carrier would have results based on their mission and objectives for possible upset recovery training. Since the multiple sub-tiers would only be dealing, at first, with one specific arena, the results could be used grist for another round(s) where consensus, via criticality ratings and discussion, is worked on. This multi-tiered approach can be used for all the issues listed above-simultaneously or sequentially. In a second, or as an extension of the first SGDP/ETE/RTD, the SME pilots can identify and sort these upset recovery maneuvers into taxonomies for those which are primary and necessary for what can be called an air carrier's "basic training" for aircrew, then for transition training and for yearly recurrent training. Again, in a tiered series of SGDP/ETE/RTDs.

The use of a FS (What type? What recovery techniques can be taught in FS and which require in-plane training? And for which planes?). What are the performance standards for each maneuver? Answers to these all would be results from such an effort. It may be possible that the large amounts of data being developed ("soft data" as they are the results of opinions and/or criticality ratings) could be handled by data & knowledge engineering (DKE) methods. Finally, these SGDP/ETE/RTD techniques can be used for many tasks requiring generating and use of specific knowledge sets.

EVALUATING THE PARADIGM IN TERMS OF KM SUCCESS

Only a few years back, a model was developed (The Jennex and Olfman KM Success Model; Jennex, 2013) that would allow, among other things, evaluating the Organizational Knowledge elicited and its use by the organization. Put another way, much of KMS work today has a focus on the knowledge elicited being of use in/to an organization. Using the KMS model can allow a measure, actually several measures, of the use-value to an organization of knowledge elicited and developed about the organization. The author sees using the KMS model as necessary in evaluating work done in knowledge management/organizational knowledge. It can also be used, retroactively, on prior KM/organizational knowledge efforts to find where and why such efforts were successful...or not. Perhaps pointing the way to additional efforts that would have more...or a chance of...successful outcomes.

As some examples: one KM Success Model measure of success is internal and external success of the knowledge being useful and used. Was the organizational knowledge set the organization generating the knowledge about itself successfully used? Was the organizational knowledge elicited in agreement with (useful to?) the objectives it was elicited for?

Another measure of KMS is knowledge quality as shown by organizational knowledge generated being accurate/correct and inclusive, being optimum...i.e., optimum being a performance-based word. In the KMS model one measure is system quality: Was the organizational knowledge generated stored, able to be retrieved and applied?.

Lastly, yet another KMS measure is service quality as shown by the performance impact of the the organization making operational the knowledge generated about itself.

It is to be hoped that, if the paradigm were used in/on real life organizational issues and problems, one could reasonably expect the Organizational Knowledge gained to be successful in many ways. Us-

ing the Jannex KMS model to evaluate any real life use of the model presented would provide data that could well be instructive and helpful to any future efforts/research,

SOLUTIONS AND RECOMENDATIONS

Of necessity, this Section of the Chapter will be rather short. Mayhap it should have been rolled into the final two Sections. Plainly put, this Chapter does not present findings, rather it shows how a new paradigm was developed from one begun in 1986 and used for many years. The Chapter delineates new components, due in the main to new technology but also to the incorporation of an older technique. It does give an example of how this new model could be used on a real life problem, in real time. At this point, the final two Sections come into play and there may be some redundancy.

FUTURE RESEARCH DIRECTIONS

As said, this Chapter is not a report on the results of prior experimentation, rather it is an attempt to meld old and new techniques with advances in technology ...in a new discipline. It is an attempt to indicate the structure of a new paradigm that can be useful in developing and using organizational knowledge. More importantly, it is also a call for research efforts to try the new procedures and validate (or not) them. Another future research task would be to see how/if using the new paradigm was a KM with KMS endeavor. Thus, this chapter provides a rough template for possibly important future research.

CONCLUSIONS

The broad spectrum of Knowledge Engineering has immensely benefitted from the new/newer technologies of the last 10-15 years. Let us begin with Knowledge Elicitation and the Delphi technique. What was a real change in Delphi techniques, the SGDP of the late 1980s into the early 2000s, has become not only accepted and used, but has a name; The ETE Delphi. Advances in computer speed, memory capacity, in communication speed not only led to the ETE but now to the ability to do a Delphi or concurrent ones in real time ..the RTD

A new arena, knowledge management has strongly impacted the knowledge elicited by its focus on organizational effectiveness. There is now a new emphasis on selectively applying knowledge from previous experiences with the express purpose of improving the organization's effectiveness. Next is Organizational Knowledge. This term has had some differing definitions; the author prefers a compilation of different knowledges and skills possessed by the employees of a large company or organization. Organizational Knowledge can identify, compile and organize these differing knowledges/skill so as to enable them to be codified and used. This effort leads back to knowledge engineering/elicitation and knowledge management.

And, in the newest step forward, one has knowledge management success..a new discipline which attempts to show how/measure the Organizational Knowledge elicited impacts the function and effectiveness of a/the organization. In point of fact we have the Jennex and Olfman KM Success Model (Jennex, 2013), At this point, one can see not only the connection of these disciplines but their interconnectivity.

Again, it must be strongly noted that the Chapter is not a report on the results of prior experimentation, rather it is an attempt to meld a modified Delphi procedure with today's KE/KM efforts and today's technology for use in developing and using Organizational Knowledge. It provides a start-point template with an example of using that template..

ACKNOWLEDGMENT

A very special acknowledgment to Dr. Murray Jennex (Editor-in-Chief of the *International Journal of Knowledge Management*), who responded to a seemingly innocuous email question by asking if I would write an article for the Journal he edited. I replied that KM was not an area of expertise. He responded that what I had asked about was indeed a KM effort and gave me a list of KM readings. He proceeded to provide guidance on the article; he was a taskmaster for which I am more than grateful. He helped me to write a much larger, more complete and better article than I did not realize I had in me. Dr. Jennex and I continued to communicate; though sadly after my major stroke, that communication has waned. Thanks to Dr. Jennex, I was able to see how much of my work was cognitive engineering through knowledge elicitation and knowledge management. I feel extremely fortunate that he was the recipient of that email query and that he chose to expend quite a lot of time and effort on me. I hope I have justified his belief in my work.

I would also like to thank Gerald M. Gibb, PhD, Captain, USNR (retired). He has been a co-researcher, co-author and an important person in civil aviation security in his own right for 35 years. We first met in 1985 and his contributions in the early stages of this Chapter are beyond measure. I have been fortunate enough to have worked with Gerald many times over the years and have had not only a professional but a personal relationship with him...both of which I treasure.

KEY TERMS AND DEFINITIONS

Consensus: Consensus is the state achieved when, if any group participant is asked, alone and outside of the group's hearing, about the consensus/results achieved by the group: their response is that they can support the consensus arrived at, no reservations.

Facilitator: A person that helps to bring about an outcome (as learning, productivity, or communication) by providing indirect or unobtrusive assistance, guidance, or supervision. At times, the facilitator can provide initial instruction and, at times again, be more proactive as to direction.

Flight Simulator: A flight simulator (FS) is a system designed to “imitate” the functions of another system (an airplane) in a real operational environment; to be a realistic substitute that responds realistically to flight crew inputs. A FS is a training device whose primary functions are 1. To present information like that which the real system would present, for the purpose of training and, 2. To provide a practice environment that facilitates and enhances the skills and knowledge of the pilot, and thus provides learning which enhances performance in the real system, the airplane. There are several types of flight simulators.

Group Dynamics: The interactions that influence the attitudes and behavior of people when they are grouped with others through either choice or accidental circumstances. Social psychologist Kurt Lewin coined the term *group dynamics* to describe the positive and negative forces within groups of people.

Ontology: A term that comes from philosophy. In KE/KM, an ontology is a formal naming and definition of the types, properties, and interrelationships of the entities that really or fundamentally exist for a particular domain of discourse. It is thus a practical application of philosophical ontology, with a taxonomy. A KE/KM ontology compartmentalizes the variables needed for some set of computations and establishes the relationships between them; thus, an ontology is used to limit complexity and to organize and structure information.

Real-Time Delphi (RTD): An advanced form of the Delphi method. The advanced method “is a consultative process that uses computer technology” to increase efficiency of the Delphi process.

Subject Matter Expert (SME): An individual who exhibits the highest level of expertise in performing a specialized job, task, or skill within the organization.

United States Federal Aviation Administration (FAA): Is the national aviation authority of the United States. As an agency of the United States Department of Transportation, it has authority to regulate and oversee all aspects of American civil aviation.

United States Federal Aviation Administration (FAA) Advisory Circulars (AC): The FAA normally publishes these which are designed to provide assistance and guidelines in complying with FARs; they serve as a “how to” template. The AC’s are titled and numbered and are not legally binding as are the FAR’s.

United States Federal Aviation Administration (FAA) Regulations (FAR): All are in the Combined Federal Regulations (CFR), Title 14, Aeronautics and Space; each a descriptive title and number; they are legally binding.

United States National Transportation Safety Board (NTSB): An independent Federal agency charged by Congress with investigating every civil aviation accident in the United States and significant accidents in other modes of transportation – railroad, highway, marine and pipeline. The NTSB determines the probable cause of the accidents and issues safety recommendations aimed at preventing future accidents.

State of the Art in Semantic Organizational Knowledge

Mamadou Tadiou Kone

International University of Grand-Bassam, Côte d'Ivoire

INTRODUCTION

Semantic organizational knowledge refers to the Semantic Web and Linked Data technologies that are applied to the principles and procedures of organizational knowledge. The aim of this chapter is to present the state of the art research in *semantic organizational knowledge*. Originally, organizational knowledge is the ability of employees of an organization to perform tasks given the collective understanding of a particular context. As human knowledge comes in many forms and shapes, previous research conducted by Nonaka (2007, chapter 3), Choo (1996) and Spender (1993), has identified the existence of several types of knowledge in organized contexts including *explicit* knowledge, *tacit* knowledge, *cultural* knowledge and *embedded* knowledge. Explicit knowledge is intuitive, based on experience, intractable and refers to knowledge known as “know-how”. It was originally defined by Polanyi (1958). The popular view of this type of knowledge is a form of knowledge encoded in organizational practices, procedures and routines. It is also transmittable in formal language as clear facts, propositions and symbols. Tacit knowledge known as “know-what”, is easy to identify, store, retrieve and disseminate. Cultural knowledge refers to being familiar with various cultural characteristics, including history, moral values, belief systems, history, and social norms. In contrast, embedded knowledge, a substantial part of organizational knowledge, is formal or informal knowledge that is locked in archives, processes and internal practices waiting to be extracted. The essence of this knowledge, either individual or collective, is often perceived as a dynamic array of experiences, values, contextual information and expert insights. When it is individual, knowledge shows an individual’s ability to demonstrate judgment in a particular situation. In contrast, collective knowledge initiatives in an organization consist of creating and sharing knowledge for improving business and increasing productivity. These initiatives may also expand externally over time and include partners and customers. From this perspective, knowledge becomes an organizational asset that can be managed, shared with partners or provided as a service to others. According to recent research, the **Semantic Web**, an extension of the current Web (Berners-Lee, 1999; May 2001), (Decker, 2000) and its related **Linked Data** concepts and techniques appear to be appropriate for solving issues of knowledge acquisition, documentation, transfer and sharing/distribution in an organizational context. In fact, these concepts rely heavily on Resource Description Framework (RDF) and Ontology. 1) The popular RDF model and syntax is a World Wide Web Consortium (W3C) recommendation in February 1999 (Heflin, 2001). An ontology provides an agreed understanding of an organization domain knowledge that rests on a common vocabulary. More precisely, an ontology defines the meaning of the terms in that vocabulary together with their inner relationships (De Araújo, 2015; Chandrasekaran et al., January 1999). It plays a central role in enabling the processing and sharing of knowledge within an accepted domain. Originally, the concept of ontology was created in the branch of philosophy that studies being or existence, the kind of things that exist. Then, the term was co-opted by Artificial Intelligence researchers to represent computational models for automated reasoning. A widely accepted and

DOI: 10.4018/978-1-7998-3473-1.ch121

interesting technical definition of an ontology that still stands in computer science is that “*an ontology is an explicit specification of a conceptualization*” (Gruber, 1993, p. 1).

The main purpose of this chapter is to present a state of the art survey of research and development in semantic Web and Linked Data applied to the management of organizational knowledge. The applications of these technologies can have a direct impact on people, internal processes and support the distribution of knowledge throughout and outside of the organization. However, these advances are not without social and cultural issues and technical challenges. To this end, a tentative structure¹ of this contribution is the following: The first section is an **Introduction** to the main topic in the Semantic Web context. A **Background** section provides details on the real nature of organizational knowledge, the Semantic Web and Linked Data. The **Focus of the Article** section presents results of our state of the art survey on R&D in semantic organizational knowledge. This survey focuses on current issues and challenges in knowledge management that could be solved using Semantic Web or Linked Data technologies. Then, some known solutions to current challenges are suggested in the **Solutions and Recommendations** section. Last, a number of research ideas are presented along the lines of our discussions in a **Future Research Direction** section. A short summary of contributions concludes the chapter.

BACKGROUND

Types of Knowledge

This section introduces the concepts of *organizational knowledge* and presents the *Semantic Web* and *Linked Data* as enabling technologies. In the modern economy, many organizations implement initiatives for the management of *organizational knowledge* for improving process performance, raising product/service quality, engaging customers and laying the ground for innovation. To reach these goals, large organizations have been investing time, energy and funds into the capture, storage, sharing and dissemination of existing collective knowledge and the creation of new one. The vast, previously unexplored, human knowledge across these large organizations, is helping them build competitive advantage on the marketplace. Polanyi (1958) was the first to explain the term “tacit knowledge” in his pioneering work in the mid 50s. The main principle of Wiig’s knowledge management model (1993) requires knowledge to be organized according to its applications. Practical dimensions of this model are completeness (relevant knowledge), connectedness (relations between knowledge objects), congruency (facts, concepts, values between the objects are consistent), and perspective and purpose (Dalkir, 2011). Then, Koenig and Srikantaiah (2000), Nonaka (1994, 1998) and Cvusgil et al. (2003) laid the foundations of the most accepted depiction of knowledge with its *tacit*, *explicit* and *implicit* dimensions (see Figure 1).

Explicit knowledge is easy to identify, capture and represent in formal languages. Examples explicit knowledge include corporate publications, internal business messages and records, intranet, relational and knowledge bases. This type of knowledge can be extracted, edited, managed, stored, retrieved and distributed within the organization. Managing explicit knowledge means creating, acquiring, sharing and disseminating it with the support of information and communication technologies (ICT).

Tacit knowledge in contrast to explicit knowledge, is inherently elusive and cannot be articulated because it rests in individuals’ mind in the form of experience gathered as insights, heuristics, intuitions, and skills difficult to share with others in formal terms (Stenmark, 2001). Tacit knowledge is hard to codify and transfer from one individual to another or to an organization. Since this form of knowledge lays the ground of intellectual capital in organizations according to Koenig and Srikantaiah (2000), it

Figure 1. The Knowledge Management iceberg

Retrieved and adapted from <https://www.k4health.org/toolkits/km/about-km>.

must be represented and managed as well. Srikantaiah and Nonaka (1991) suggest that explicit and tacit knowledge are strongly interrelated in that each contributes to the understanding and support of the other. In addition, they are part of an effective organizational knowledge management.

Semantic Web and Linked Data

In the early 2000, a new vision of the Web of data called the **Semantic Web** was proposed in the form of an extension of the current Web of Hypertext Markup Language (HTML) documents. Its objective would be to facilitate human-computer collaboration. Berners-Lee explained the term Semantic Web in 2006 as: “*The Semantic Web isn’t just about putting data on the web. It is about making links, so that a person or machine can explore the web of data. With linked data, when you have some of it, you can find other, related, data.*” (Berners-Lee, 2006) To support this new framework, an ensemble of technologies including the Resource Description Framework (RDF) based on XML syntax, its related RDF schema, the Darpa Agent Modeling Language (DAML), the Ontology Web Language (OWL), (W3C, February 2004) the Simple Knowledge Organization Systems (SKOS), are developed by the World Wide Web Consortium headed by Berners-Lee. An illustration of the Semantic Web technology stack is displayed in Figure 2 below.

Figure 2. The layered Semantic Web technology stack

In the traditional document Web, hyperlinks relate only two HTML documents and leave out the fine-grain relationships between specific entities included (Savage, June 2017). To make up for this lack of expressiveness of the HTML language, the Consortium introduced the concept of *Linked Data* (Bizer, 2009). It refers to a collection of interrelated data sets that rests on the known HyperText Transfer Protocol (HTTP) technology (Fielding et al., 1999) and the (Berners-Lee et al., 2005).

To turn the Web of data into reality, the current Web extends into a global space where related data, previously isolated, becomes connected. In computing, Linked Data is a method of publishing structured data as interlinked entities in RDF format and the Uniform Resource Locators (URIs). Its purpose is to serve Web pages for human reading and more importantly for computers automatic processing. Here data is represented in the form of RDF triples as (*subject, predicate, object*). The *subject* (source of the relationship) and *object* appear as URI references that represent resources. The *predicate* (known as property), also represented as a URI reference, is the element that tells us how the subject and object are related. A predicate is also a *first-class object* because it may be used as subject or object in another statement. It is good to know that the subject and the predicate of a statement must be resources whereas the object has the option of being a resource or a literal (Decker, 2000). The representation of the many layers of information as a collection of triples, generates a data model where relationships between elements appear as arcs labeled with properties names in a directed graph. This particular graph is in turn parsed by the **Sparql Protocol And RDF Query Language (SPARQL)**, a powerful query language and widely used Application Programmer Interface (API) for accessing linked data collections online.

The following example directly related to the publication of this encyclopedia could help visualize this model more clearly. In order to specify the link between an author named *John* and the book editor named *Mehdi Khosrow-Pour*, conventional relational databases must contain tables that describe these two persons and their related primary/secondary key identifications. However, this link does not provide any description of the actual semantics of this relationship of data. The database knows natively that the two elements are related but has no clue of how they are link. With the help of the RDF data model, this link can be annotated with semantic meaning which relates the elements through the triple <John><is published by><Mehdi Khosrow-Pour>. Details are provided in **Figure 3** and below.

```
<John> <is an> <author>.
<John> <is a colleague of> <Martha>.
<John> <is born on> <January 1st, 1986>.
<John> <published in> <Ency. of Organizational Knowledge, Admin., and Tech.>.
<Encyclopedia of Organizational Knowledge, Admin., and Tech.> <is edited by>
<Mehdi Khosrow-Pour>.
```

Figure 3. Connected graph of the triples example

<the Web page 'GI Global Call for Chapters - E.O.K.A.T.'> <is about> <Ency. of Organizational Knowledge, Admin., and Tech.> <John><published in><Ency. of Organizational Knowledge, Admin., and Tech.>

Linked Data is at the heart of the Semantic Web in terms of large scale integration and reasoning on the Web of data. Berners-Lee (2006) outlined a set of guidelines known as the “*Linked Data Principles*”, for publishing and relating data on the Web as part of a single global data space. Given its distributed nature, Linked Data technology offers a strong support for the integration and management of internal or shared enterprise data (Baldassare et al. 2010). It fosters enterprise cooperation in data sharing with little coordination. There exist a number of experimental methods for capturing and expressing tacit knowledge within a Linked Data set (Di Iorio, 2019).

ISSUES IN KNOWLEDGE MANAGEMENT

This section explore key issues in organizational knowledge representation and management. In spite of the impressive amount of theoretical and conceptual work, the knowledge management research community must rethink some fundamentals including the theoretical aspect of knowledge itself and knowledge management processes (CEN, 2004; Heisig, 2009). One of the challenges of current organizational knowledge systems is to identify and integrate vast amount of structured or unstructured data from heterogeneous sources. Data sets in corporate knowledge must be reachable and editable from different perspectives and users within the organization. On the other hand, the existence of multiple computer systems creates heavy costs for:

- storing redundant data;
- automating data transfer between systems;
- updating or replacing obsolete software and related applications;
- organizing and reformatting data moved from one system to another.

In addition, the planning systems of organizational resources have an inherent limitation in processing the meaning of concepts in knowledge bases. This is where the Semantic Web comes into play by providing new methods of data management and representation of meaning through ontologies (Fridman, 1997).

Knowledge Creation Issues

The idea of a hybrid knowledge environments (Davenport, 1998) including humans and computing resources, could support knowledge creation in an enterprise. It also helps overcome inherent technological challenges and take into account the enterprise business needs. However, the discussion around enterprise system failures does not appear to consider the fact that modern enterprise systems go through a trial or evaluation period before their definitive adoption in an enterprise. That is to say, an enterprise system no longer imposes its own logic on a company's strategy, organization, and culture. In the concept of Core Organizational Knowledge Entities (COKE), an ontology, expressed through disjunctive logical programming, helps capture the evolution of business processes. This concept described by **Gualtieri and Ruffolo** (2005) includes 2 distinctive levels of ontologies: 1) the top level ontology which refers to concepts characterizing organizational background and 2) the lower level ontology designed for the

COKE. A similar approach that exists, considers a layered set of ontologies of a relevant sub-domain (Ammann, E. et al., 2011). These ontologies describe the real life domain knowledge ontology together with the logic for reasoning. and support interoperability (Swartout 1999; Gualtieri 2005).

Knowledge Sharing and Dissemination Issues

Over the last two decades, the issue of knowledge sharing in organization has been the focal point of much research and debate. Knowledge is created and transferred by individuals (Minbaeva, 2004; Nonaka & Takeuchi, 1995). Organizational culture, access to appropriate technology and its integration appear to have substantial impact on organization success (Raja, 2011). Research also found that solving issues around culture and employees behavior is a prerequisite to any technical implementation within the organization. Given this information, several researchers proposed innovative techniques, tools and approaches based on the Semantic Web and Linked Data for an efficient KM. During this long journey, the focus of semantics in KM has evolved from knowledge containers in textual form to the application of Semantic Web technologies. More precisely, these technologies refer to ontologies originally introduced in artificial intelligence, to support knowledge sharing and re-use. This shift in perspective paved the way for better KM solutions including knowledge elements of varying granularity. According to **Fensel** (2003), this whole new perspective in KM created a number of issues including:

- 1) *knowledge integration*: The development of KM applications in organizations requires a seamless integration of interrelated knowledge into a coherent corpus. This helps avoid development overhead.
- 2) *knowledge categorization*: User interactions, patterns of behavior and context suggest new semantic categories and relations.
- 3) *knowledge personalization*: It refers to user experience and expectations in order to avoid information overload and for delivering the right knowledge. With the support of Semantic Web with ontologies, it is possible to provide semantic information about a user's interests and
- 4) *knowledge access*: For some time, fields including genomics, astrophysics and biochemistry generated large amount of data with virtually no semantic means.

Kings et al., (2007) advocates in his models of knowledge sharing, the use of ontologies for the improvement of knowledge management in organizations where social and technical context are taken into account. **Nonaka** and **Takeuchi** contended that the sharing and dissemination of knowledge in organizations is a prerequisite to its use (Nonaka & Takeuchi, 1995). However, this aspect of knowledge management relies very much on the organizational culture and the existence of technology capable of processing explicit knowledge. According to **Pasquariella** (2003), knowledge sharing and dissemination is essential to organizations in that it generates new knowledge leading to competitive advantage. In (**Mentzas** et al, 2007), the reader discovers new approaches that appear as a substitute to traditional knowledge sharing techniques and practices in organizations. In their contribution, the authors focused knowledge exchanges that treat knowledge assets with Semantic Web capabilities as tradable goods. **Stojanovic** et al. (2007), proposed a framework for managing organizational knowledge on the Semantic Web where differently formatted knowledge can be collected from various sources, stored in known formalism (**Mentzas** et al, 2007) and processed (**Staab**, 2001).

Knowledge Acquisition Issues

In contrast to the traditional perception of an organization where knowledge is acquired through procedures, training and rules; the “learning organization” empowers individuals and turns technology into a facilitator. Sicilia (2005) suggested that learning styles can be included within ontologies and semantic methods may support the sharing of knowledge and experiences. More specifically, Semantic Web technologies provide the necessary infrastructure to support organizational learning mechanisms. Here ontologies refer to descriptions of learning objects, organization fundamentals and resources. He also proposed the concept of “semantic learning organization” as an entity where semantic-mediated learning acts as a catalyst to move the organization to a desired state. The implementation of this vision where the Semantic Web plays an essential role is not without serious challenges. Sicilia insists that “the creation and maintenance of large, shared conceptualizations is a problem in itself” and the implementation of specific languages requires advanced tools and the need to align an organization and its individual members’ needs and satisfaction. A number of studies show that organizational knowledge acquisition benefits substantially from emerging techniques. However, according to Zolhavarieha (2007), a number of issues including the quality, relevance and reliability of the extracted knowledge, still persists. These studies also mention that as knowledge acquisition becomes more complex, so does its semantics. In addition, they also note two knowledge-acquisition issues that can be addressed by Semantic Web technologies: data format and content heterogeneity and the lack of semantic analysis.

SOLUTIONS AND RECOMMENDATIONS

The Semantic Web and Linked Data technologies can provide the appropriate supporting framework for connecting heterogeneous data sets within an organization. These technologies not only help structure and uncover the meaning of this data but they also contribute in solving the known issues related to distributed and heterogeneous data. The recommended approach in implementing a Semantic Web and Linked Data is highlighted in the following steps: the raw data is transformed into the Resource Description Format (RDF) knowledge base of triples (*subject, predicate, object*). That is to say, statements about resources are formalized for better processing. As stated in the “Semantic Web and Linked data” sub-section, subject, predicate and object are materialized as URI references or literals. Central to the implementation of the Semantic Web in organizational settings, are ontologies. Their main purpose is to solve the inter-operation juggernaut in large organization systems. In this perspective, explicit knowledge is ascribed metadata extracted from the domain/topic of interest to create a relevant ontology. With this shared ontology, systems with different syntax, structure and format can engage in a productive exchange, search and retrieval of information process. By its nature, an ontology includes multiple different views and vocabularies. As part of the applications of semantic Web services, an ontology also raises knowledge structures to higher levels including intelligence. Therefore, semantic techniques together with ontologies could help in managing integration in organization knowledge.

Another interesting solution is the **Simple Knowledge Organization System** (SKOS), an element of the Semantic Web family of standards (World Wide Web Consortium, 2009) and part of the Linked Data ecosystem. It is conceived with thesauri, classification schemes, taxonomies, and structured vocabulary. Its objective is to enable easy publication of these vocabularies as linked data. Several initiatives are exploring SKOS for the management of knowledge in organizations. The implementation of SKOS in organizational knowledge allows multiple actions including:

- a) identification of concepts using URIs,
- b) labeling with lexical strings in natural languages,
- c) assigning notations (lexical codes),
- d) linking to other concepts and organizing into informal hierarchies,
- e) aggregating into concept schemes and ordered collections,
- f) mapping to concepts in other schemes.

FUTURE RESEARCH DIRECTION

Over time, KM as a multidisciplinary science, has benefited from a variety of academic contributions and an extensive set of organisational practice from industry and society. As a result, KM research needs critical research perspectives that take into account themes related to individuals, communities and industries. These themes will bring balance and a whole new perspective in the KM landscape. Future research on Semantic Organizational Knowledge should naturally go along the lines of advances in the fields of Semantic Web and Linked Data. That is to say, future research agenda in this field could be influenced by the evolution of Linked Data in connection with Artificial Intelligence including Big Data, Machine Learning and Deep Learning. For example, recent surveys on Linked Data research (Bizier, 2009; Heath 2011) show an increased interest in building deep learning data sets, architecture search and compressing neural networks. These approaches are paving the way for the future of Deep Learning. In addition, future research in Machine Learning is currently heading towards two directions illustrated in the following questions: 1) how is it possible to generalize a concept from studying a small sample set? 2) how should we apply knowledge gained from experience to new or dynamic contexts? Besides, the Semantic Grid, defined as an extension of the current Grid with information and services clearly identified (Geldof, 2004), is converging with the Semantic Web to explore the advancement of Semantic Organizational Knowledge.

CONCLUSION

This chapter presented the state of the art survey on semantic Web and Linked Data technologies for solving issues related to organizational knowledge. The concepts of organizational knowledge, Semantic Web and Linked Data are presented. Then, a description about the Semantic Web and Linked Data underlying technologies including RDF, RDF schema, DAML, OWL and the SKOS are given. A comprehensive survey on R&D in semantic organizational knowledge is proposed. Here Knowledge is clearly considered through its explicit and tacit dimensions to highlight applications domains of Semantic Web and Linked Data technologies. That is to say, this chapter demonstrated how these technologies have been used to effectively support all aspects of knowledge acquisition, creation, sharing and dissemination.

KEY TERMS AND DEFINITIONS

Explicit Knowledge: Explicit knowledge is knowledge that can be verbalized, stored, accessed, and shared with others. Explicit knowledge is often seen as complementary to tacit knowledge in that you need both to draw a complete picture of organizational knowledge.

Linked Data: It is about using the Web to connect related data that wasn't previously linked, or using the Web to lower the barriers to linking data currently linked using other methods. More specifically, Linked Data is the set of recommended best practice for exposing, sharing, and connecting data, information, and knowledge on the Semantic Web using Uniform Resource Identifier (URI) and Resource Description Framework (RDF).

Organizational Knowledge (OK): It refers to the collective knowledge and skills possessed by employees of an organization. This knowledge exists in the form of intangible company asset that needs to be shared and processed in order to provide competitive advantage.

Semantic Organizational Knowledge (SOK): This concept refers to technologies of the Semantic Web and Linked Data applied to the principles and procedures of organizational knowledge.

SPARQL Protocol and RDF Query Language (SPARQL): It is a powerful query language and widely used Application Programmer Interface (API) for accessing linked data collections online.

Tacit Knowledge: This is knowledge acquired through personal experience that is difficult to express. It is also known as the individual know-how, techniques, processes, and expertise that is considered embedded in the organization's knowledge base.

Uniform Resource Identifier (URI): It is a string of characters that uniquely identifies a particular resource (virtual or physical) that is part of a computer network. Two types of URIs exist: the Uniform Resource Locator (URLs) and Uniform Resource Names (URNs) which follow known syntax and protocols to. The first expresses an address whereas the second defines a name space for persistent object names.

Influential Factors on Reverse Knowledge Transfers in Multinational Organizations

INTRODUCTION

Knowledge plays a pivotal role in the competitiveness of firms as both a resource in itself – which is rare, firm-specific, and difficult to imitate or substitute – and an integrating factor that makes other intangible resources and capabilities unique, especially in dynamic environments.

Knowledge has also a social dimension within firms. Hence it is important that firms develop a positive culture so that the utilization of individual's knowledge can be used and thereby makes firms compete favorably in the market. As such, firms need not only to develop a better knowledge base, but also need to manage knowledge better. For that, firms need to develop a teamwork effort so that the utilization of knowledge is useful for the firm (Omerzel & Gulev, 2011).

Globalization has turned organizations into highly complex and competitive environments where information and knowledge are the main sources of sustainable competitive advantage (Nonaka & Takeuchi, 1995; Teece, Pisano, & Shuen, 1997). With the globalization of the economy, the internationalization of the firms has become an increasingly important activity for their growth and survival (Dicken, 2015; Moreira, 2009). Although there are numerous theories that explain how firms internationalize, knowledge is almost taken for granted in most of them (Ribau, Moreira, & Raposo, 2015). Moreover, very few scholars address the importance of knowledge as a competitive advantage for multinationals to compete (Moreira, 2009; Ribau et al., 2015).

Multinational organizations need to be seen as global knowledge transfer systems where multiple knowledge flows happen simultaneously every minute between headquarters and local clusters, headquarter and subsidiaries and also among subsidiaries. Furthermore, in order to improve international positioning, these organizations must deal with and try to take advantage from different temporal, cultural, linguistic and spatial contexts (Demarest, 1997; Spender & Grant, 1996). Knowledge transfer involves sharing, filtering and presenting knowledge. This process is successful when the knowledge receiver changes its behaviour or performance, due to the knowledge sender's transfer (Argote & Ingram, 2000).

On one hand, headquarters (thereby written HQs) are irreplaceable sources of new knowledge for the subsidiaries, since they possess valuable intangible assets and capabilities, which might be used by the subsidiaries in their local markets. However, on the other hand, the local knowledge created and transferred from the foreign subsidiaries to the headquarters has proved to be very beneficial to the

DOI: 10.4018/978-1-7998-3473-1.ch122

productivity and local performance of the multinational, improving the formulation of global strategies, facilitating the access to external resources and supporting both research and development (R&D) and new products development activities leading to productivity gains to the multinational (Ghoshal, 1986; Ishihara & Zolkiewski, 2017).

Subsidiaries can contribute to the overall multinational knowledge with local expertise and market intelligence. The expertise concerns input, productivity and output processes. Whereas market and business intelligence refer to information about clients, competitors and suppliers, representing the most valuable knowledge to the firm but least transferred one (Ambos, Ambos, & Schlegelmilch, 2006; Gupta & Govindarajan, 1991). Although there are numerous researches on the importance of several types of knowledge flows within multinationals (e.g. Crespo, Griffith, & Lages, 2014; Yang, Mudambi, & Meyer, 2008), the aim of this chapter is to deepen the literature specifically on reverse knowledge transfers in which knowledge flows from the subsidiary (the sender) to the HQs (the receiver) that receives, absorbs and applies it to obtain and exploit global competitive advantage.

This chapter seeks to explore the main key success factors that influence Reverse Knowledge Transfers (RKTs) within multinational corporations (hence referred as MNCs). The chapter categorizes those knowledge transfers within four main groups: subsidiary's characteristics; knowledge characteristics; relationships between HQs and subsidiary; and the central outcomes of these knowledge flows to the organization.

This chapter is divided in four sections. After this introduction that comprises the first section, background information is presented in section two. Section three addresses the main focus of the chapter: the four main groups of RKT. Section four presents the solutions and recommendations. Section five addresses the future research directions. Finally, section six presents the main conclusions.

BACKGROUND

As stated before, knowledge is considered the main source of companies' competitive advantage (Nonaka & Takeuchi, 1995; Teece et al., 1997). Since MNCs are divided into several agencies, they must handle knowledge transfers in different directions, such as conventional or vertical transfers (from HQs to subsidiaries), lateral or horizontal transfers (between subsidiaries) and reverse transfers or RKT (from subsidiaries to HQs). The latter, while being extremely valuable in transferring knowledge and underpinning the MNC's strategy, faces several obstacles to succeed.

This chapter's contribution can be divided in terms of RKT factors into four main groups: characteristics of subsidiaries, characteristics of knowledge, characteristics of the relationship between HQs and subsidiaries, and outcomes of RKT. The first group, which is one of the most explored topics in literature, is the subsidiaries' characteristics, namely the influence subsidiaries have under the strategy development, the internal and external embeddedness of these divisions, the subsidiary's country of origin, as well as the entry mode chosen to initiate the commercial relations in the given country.

The characteristics of the knowledge itself are very relevant to explain the RKT, specifically in terms of relevance, explicitness and complexity (Crespo et al., 2014; Ishihara & Zolkiewski, 2017; Yang et al., 2008).

The relationship between subsidiary and HQs is an extremely interesting area, although difficult to exploit and sometimes achieving contradictory results. It explores aspects such as the ability to disseminate and absorb knowledge, human resources practices and the control and coordination mechanisms adopted in each subsidiary.

In spite of being very scarce, information was also gathered on the research carried out on the results of RKT in terms of performance or productivity gains to the MNC, based on the work of Ambos et al. (2006) and Driffield, Love, and Yang (2016).

FOCUS OF THE ARTICLE

The main focus of this section is to address RKTs based on the main groups referred in the introduction.

Subsidiaries' Characteristics

This subsection analyzes the subsidiaries' characteristics, bringing into focus the subsidiary's elements that influence the success of RKT such as autonomy, capacity and willingness, age, influence, strategic role, entry modes, location and embeddedness.

Autonomy

The autonomy of a subsidiary determines the degree to which it has the power to decide on MNC's strategic issues. As autonomous subsidiaries can exploit their business and local market opportunities by taking advantage of external sources of knowledge, they normally engage in more RKTs vis-à-vis less autonomous subsidiaries (Silveira, Sbragia, Lopez-Vega, & Tell, 2017). Regarding the use of coordination mechanisms, Rabbiosi (2011) demonstrated that when subsidiaries are more autonomous, choosing technological coordination mechanisms is a better option.

Capability and Willingness

In order to understand the subsidiary's capability to transfer new knowledge, HQs' managers should evaluate the adequacy of training routines and performance appraisals, the degree of the subsidiaries' formal integration, and the frequency of communication between subsidiaries and HQs (McGuinness, Demirbag, & Bandara, 2013), as the perceived capability of the subsidiary has a significant positive impact on RKT (Nair, Demirbag, & Mellahi, 2016).

The motivation or willingness of the subsidiary's employees to transfer knowledge has a positive impact on RKT. This motivation depends on: good human resource management practices (particularly compensation and promotion systems); the degree of informal integration of the subsidiary, the frequency of communications between HQs and subsidiaries (McGuinness et al., 2013); the extent of external embeddedness; and shared values between HQs and subsidiaries (Najafi-Tavani, Giroud, & Sinkovics, 2012).

Additionally, RKT may benefit more from subsidiaries with corporate language proficiency (Pelto-korpi, 2015).

Age

Generally, older subsidiaries transfer more strategic knowledge to the MNC when compared to the younger ones (Rabbiosi & Santangelo, 2013; Silveira et al., 2017), as older subsidiaries have more information, resources, R&D skills, experience, as well as better integration with the HQs. However, sometimes the participation in RKT is higher for younger subsidiaries, since they adapt faster to the demands of the

markets and to the organizational contingencies of the MNC (Silveira et al., 2017). Moreover, the positive link between age and knowledge relevance depends on the entry mode of the MNC, which means that acquired subsidiaries and/or majority-owned joint ventures are better off than Greenfield subsidiaries in RKT (Rabbiosi & Santangelo, 2013).

In addition, for young subsidiaries it is important to adopt socialization mechanisms to improve especially internal embeddedness (Najafi-Tavani et al., 2012). Moreover, in old subsidiaries there is a positive relationship between internal and external embeddedness and RKT (Najafi-Tavani et al., 2012).

Internal and External Embeddedness

As subsidiaries are normally created to explore and develop knowledge and competences on foreign markets, external or local embeddedness with suppliers and customers, as well as internal embeddedness between the subsidiaries and the HQs, are essential for both the development of MNCs' strategic knowledge MNCs and successful RKTs (Najafi-Tavani, Zaefarian, Naudé, & Giroud, 2015; Silveira et al., 2017). Thus, the information about local market collected by the subsidiaries has a positive impact on mechanisms of formalization, integration and socialization (Jeong, Park, & Chae, 2017).

Influence

Studies have shown that transferring more knowledge contributes to the subsidiaries' influential power on the MNC's strategic future. The increase in the power of subsidiaries is important, since they become more autonomous, maintain a relationship of trust with HQs and get more attention from the parent company. Enhancing subsidiaries' influence is also fundamental to HQs, because it is easier to obtain specific and local knowledge from the subsidiaries (Najafi-Tavani et al., 2015). The subsidiary's ability to exert influence on corporate strategic decisions strongly depends on its contribution to the HQs' knowledge base. Furthermore, the relationship between internal and external embeddedness and influence is mediated by the knowledge developed by the subsidiary and RKTs (Najafi-Tavani, Giroud, & Andersson, 2014).

Location

As most developed countries have infrastructural conditions, business support institutions and legal environments favorable to internationalization, it is understandable that subsidiaries located in developed countries create and transfer more knowledge compared to subsidiaries in developing countries (Ambos et al., 2006; Rabbiosi, 2011; Silveira et al., 2017). In the same vein, RKTs are most beneficial when the country of the knowledge sender has more competitive strength than the country of the knowledge recipient (Ambos et al., 2006). Conversely, the location of the subsidiary may have a negative effect on the relationship between knowledge relevance and RKT market (Yang et al., 2008).

According to Gupta and Govindarajan (2000), the economic level of a country affects the perception of value that the HQs have of knowledge accumulated and created by the subsidiaries of that country (Li, Barner-Rasmussen, & Björkman, 2007). With this in mind, subsidiaries located in more developed countries transfer more knowledge to other corporate units compared to the knowledge transferred by subsidiaries of less developed countries. Moreover, social interaction, trust and shared vision are more prominent in subsidiaries in less developed countries (Li et al., 2007). However, the relationship between

the social interaction and the location of the subsidiary is not relevant, because social interactions do not necessarily lead to a greater learning capacity, as was the case of Chinese subsidiaries (Li et al., 2007).

In addition, the level of a country's economic development and the strength of its institutional structures have a positive effect on the MNC's performance, through RKT, especially in countries where there is a prominent protection of intellectual property rights (Driffield et al., 2016).

Entry Modes

Concerning the entry modes, the subsidiaries' productivity effect on the parent company's performance is greater in acquired subsidiaries, particularly when there are similarities in the industry they are operating. The only case in which subsidiaries upstream of the HQs' supply chain generated significant productivity effects on the parent company are those subsidiaries specialized in R&D activities (Driffield et al., 2016).

In order to compare the subsidiary's innovation capacity and entry mode, it should be borne in mind that for low levels of innovative capacity, Greenfield subsidiaries transfer more knowledge than acquired subsidiaries. This is explained by the fact the language, culture, routines and organizational characteristics of newly created subsidiaries are compatible with those of the HQs. This contrasts with the behavior of acquired subsidiaries, which still need to get integrated into the internal network of the MNC to overcome the incompatibilities that may exist. On the other hand, as acquired subsidiaries are already incorporated in the local network, they can transfer more knowledge than the Greenfield subsidiaries, which still need to invest time and money in the development of a local network (Mudambi, Piscitello, & Rabbiosi, 2014).

Strategic Roles

Subsidiaries can assume one of four strategic roles, regarding the behaviors and patterns of knowledge flows (Gupta & Govindarajan, 1991): Global Innovators; Players; Local Innovators; and Implementers.

Subsidiaries behave as Global Innovators when they are the main source of knowledge for the other organizational units. When subsidiaries create knowledge, but are not self-sufficient in terms of their creation, they behave as Players. Implementers are those subsidiaries that invest little in the creation of knowledge and strongly depend on knowledge transfers from HQs or other subsidiaries. Finally, Local Innovators are subsidiaries that are responsible for generating almost all their local know-how (Gupta & Govindarajan, 1991). Generally, Players tend to transfer more beneficial knowledge to HQs than the other subsidiaries (Gupta & Govindarajan, 1991; McGuinness et al., 2013).

Conversely, in order to draw conclusions about the subsidiaries that transferred more knowledge to HQs Rabbiosi (2011) relied on the three roles of the subsidiaries, identified in Ghoshal's (1986) doctoral thesis: Implementer; Contributor; and Innovator. Implementer subsidiaries are units that adapt products to local market needs. Contributor subsidiaries usually take advantage of MNC's knowledge. Finally, Innovator subsidiaries are normally established to increase or create new technological skills for the whole MNC. Rabbiosi (2011) concluded that Contributors and Innovators subsidiaries transfer more knowledge to HQs than Implementers.

Knowledge Characteristics

This subsection addresses the content that is being transferred in terms of its complexity, relevance and explicitness, which is also essential to understand how RKT happens.

Complexity

As a result of the increasing specialization and sophistication of R&D activities, companies need to acquire and relate knowledge of very different areas to develop new products according to the different variety of markets, which makes knowledge more complex. Nevertheless, studies involving Brazilian MNCs have shown that the complexity of knowledge has a positive impact on RKT, because in spite of complex knowledge transmission involving more costs and barriers, RKT will be transferred anyway as it is the most valuable type of knowledge for HQs (Silveira et al., 2017).

Relevance

Knowledge relevance has a positive impact on RKT (Driffield et al., 2016; McGuinness et al., 2013; Nair et al., 2016). The relevance of knowledge transferred may be influenced by the subsidiary's country, as developed countries tend to transfer more strategic relevant knowledge to the HQs (Yang et al., 2008). The degree of firm's centralization (McGuinness, Demirbag, & Bandara, 2013) and the use of formalization integration and socialization mechanisms affect positively the relevance of knowledge created (Jeong et al., 2017; McGuinness et al., 2013). Consequently, if the knowledge transferred by subsidiaries is seen as of added value to the HQs, the subsidiaries' capability will be recognized (Nair et al., 2016) and take advantage of the market knowledge acquired by the subsidiaries (Jeong et al., 2017).

Explicit and Tacit

As tacit knowledge is more abstract and contextualized, it is more difficult to articulate and transfer (Crespo et al., 2014), which can weaken RKT (Ishihara & Zolkiewski, 2017). Although tacit knowledge cannot generally be taught, it may nevertheless be easily transferred through job rotation, training, storytelling, and forums (Rollett, 2003). As a result, MNCs need to invest to make tacit knowledge explicit as it is vital to the success of RKT, especially when cultural distance is small (Crespo et al., 2014).

Relationship Between HQs and Subsidiaries

Studies have generally paid more attention to the HQs side when investigating RKT. However, in order to complement this knowledge, it is pertinent to study the relationship between the two actors participating in these knowledge transfers. This section addresses not only how the HQs control and manage the subsidiaries, in the matter of coordination or control mechanisms and RH practices, but also the capacity of each part to absorb and disseminate knowledge, as well as the distance between the parties.

Absorptive and Disseminative Capacities

The success of RKT is positively related to the parent's absorptive capacity (Ambos, Ambos, & Schlegelmilch, 2006; Nair, Demirbag, & Mellahi, 2016), which depends on the establishment of a positive learning environment, a technical knowledge infrastructure (Nair et al., 2016) and the use of formalization, integration and socialization mechanisms (Jeong et al., 2017). This is important for the competitive wellbeing of MNCs as previous knowledge affects the degree of receiver's absorptive capacity (Ambos et al., 2006; McGuinness et al., 2013).

In a complementary perspective, Ishihara & Zolkiewski (2017) revealed the importance of heeding capacity – i.e. HQs' ability to overcome cultural and linguistic barriers through willingness and active listening – vis-à-vis disseminative capacity for the reverse knowledge transfer, especially when the subsidiary's disseminative capacity is weak – namely, when they are not proficient in English, for example (Ishihara & Zolkiewski, 2017).

In addition, the commitment of HQs can moderate the relationship between communication media richness and the RKT itself (Peltokorpi, 2015). There is also evidence to confirm the positive relationship between the HQs' absorptive capacity and the market knowledge application (Jeong et al., 2017).

Beyond absorptive and disseminative capacities, other characteristics of receivers and senders need to be highlighted, namely their communication competencies, the personal relationships they established, knowledge previously acquired and individual learning styles as they influence success of RKT (Rollett, 2003).

Distance

Distance has been studied to explain the knowledge transfer process in a multinational context. This construct can be divided into four categories: cultural, linguistic, economic, geographical and relational distance.

Cultural, linguistic and geographical distances affect the use of personal mechanisms of coordination, because they may involve people from different cultural backgrounds. On the contrary, the technological mechanisms and their code nature do not influence the knowledge transfer effectiveness between distant multinational units, since when the content is codified and transferred by computers, context is not really relevant (Ambos & Ambos, 2009).

Although there is evidence that economic and physical distances reduce the positive impact the subsidiary's performance has on the parent company (Driffield, Love, & Yang, 2016), the geographical distance does not have a clear impact on the effectiveness of RKT and does not represent a constraint to social and organizational relationship building between the two corporate units, thus, not influencing the cultural and relational distance (Jasimuddin, Li, & Perdakis, 2015).

In spite of being evidence proving that the greater the cultural distance, the lower the RKT (Crespo et al., 2014; Jasimuddin et al., 2015), other studies could not validate this relationship (e.g. Ambos et al., 2006). Complementarily, the relational distance between HQs and subsidiaries also negatively affect knowledge transfers (Jasimuddin et al., 2015).

Expatriates

There is no doubt that expatriation (also known as corporate expatriation) and repatriation involve transferring an executive from HQs or a subsidiary to another subsidiary of the company, located in a different country (Dobrai, Farkas, Karoliny, & Poór, 2012). The latter involves the inverse process of expatriation as it corresponds to the first job of an individual/manager after returning from an international assignment, that normally does not last more than two years – which can play a crucial role in the RKT process.

Expatriation can be short- or long-termed. The capability to transfer knowledge is higher if the expatriation program is short-termed (less than a year, one to two weeks, or involving frequent trips). These short experiences allow employees to acquire more knowledge and global competencies, making then better teachers/trainers. However, motivation and will is higher when the expatriation program is long-termed, as long periods of time at a foreign subsidiary allow expatriates to have more autonomy

and accountability in terms of performance and to show more commitment and willingness to perform a better job (Minbaeva & Michailova, 2004).

The knowledge transfer depends on the expatriates' ability and motivation, disseminative capacity, technological and management competencies (Dobrai et al., 2012). However, the knowledge characteristics, the receivers' absorptive capacity and the relationship between sender and receiver are also important (Dobrai et al., 2012). From another angle, the RKT of repatriates is also positively influenced by their disseminative capacity, which is related to the level of acquired knowledge and the company's whole international assignments policy. However, the firm's help and support during the expatriation and/or repatriation processes does not affect knowledge transfer (Sanchez-Vidal, Sanz-Valle, & Barba-Aragon, 2016).

Frequency of Communication

As the communication between organizational units become more frequent, the higher the ability to process information crucial to innovation processes and, consequently, the better the knowledge transfer (Crespo et al., 2014; Gupta & Govindarajan, 1991; McGuinness et al., 2013).

Coordination Mechanisms

The relationship between subsidiaries and HQs can be easier should they use coordination mechanisms, which can be personal or electronic. The personal coordination may involve the participation of subsidiaries' management within international teams or projects, staff transfer and the organization of committees and meetings (Rabbiosi, 2011). These are crucial to the routine coordination of all operational units (Ambos & Ambos, 2009). The electronic mechanisms allow all employees to codify, store and access knowledge. Their main purpose is to maximize resources that are incorporated in a unit's network separated by time and space. The electronic mechanisms use infrastructures that include tools such as business intelligence, coordination software, organizational learning and knowledge mapping (Ambos & Ambos, 2009). According to Ghoshal (1986), subsidiaries characterized as 'contributors' and 'innovators' transfer more knowledge to the HQs. As such, more personal mechanisms of coordination should be implemented in innovator and contributor subsidiaries. The electronic mechanisms should be used especially in contributor subsidiaries, which experience less autonomy than the others (Rabbiosi, 2011).

Taking into account Bartlett and Ghoshal's (1990) typology, when MNCs resort to innovations generated by their subsidiaries, MNCs tend to use resources and capabilities of their geographically dispersed units, which contribute to the developments of the MNC's competitive position. As such, knowledge involves a world-wide scientific and technological expertise in geographically dispersed units that needs to be coordinated.

Finally, the extent of shared values between the subsidiaries and HQs (Najafi-Tavani et al., 2012) and the communication media richness (Peltokorpi, 2015) affect RKT. The implementation of socialization mechanisms improves the relationship between a subsidiary and its parent company, the amount of shared values for both young and old subsidiaries, and also the extent of RKT themselves (Najafi-Tavani et al., 2012). Parent companies can benefit more from RKT if they use socialization mechanisms with older subsidiaries (Rabbiosi & Santangelo, 2013). The use of socialization mechanisms may improve the extent of internal embeddedness for both acquired and Greenfield subsidiaries (Najafi-Tavani et al., 2012).

Control Mechanisms

According to Ghoshal and Bartlett (1990), managing the interorganizational network within the MNC is a very complex task as there are different networks within the MNC. Moreover, there are also different control mechanisms and levels of formalization.

Centralization is a control mechanism of the HQs on the subsidiaries, which restricts the decision-taking to the HQs. Formalization allows the HQs to implement decision-taking power using strict routines, rules and procedures (Gupta & Govindarajan, 1991).

When these types of mechanisms are used, the communications between HQs and subsidiaries are more frequent (Crespo et al., 2014) and very important when RKTs are at stake especially involving different degrees of innovative activities among hierarchies (Bartlett & Ghoshal, 1990).

Human Resources Practices

Human resources (HR) play an important role in knowledge management. The most important HR practices related to knowledge management are the ability to assure personal credibility (such as achievement of goals and communication competencies), the change of management capacities/competencies and the appropriate business knowledge HR possess (Dobrai et al., 2012). As such, it is not usual to rely on external service providers to provide HR's functions related to knowledge management in MNCs as those functions depend on the ability and motivation of the person to transfer knowledge as well as on his/her communication skills. As a result, the training and local development (provided in the subsidiary) and informal workplace learning are the most effective learning methods (Dobrai et al., 2012).

It should be highlighted that the more similar the practices used both within HQs and subsidiaries, the greater the effectiveness of the knowledge transfer (Ambos & Ambos, 2009).

Outcomes

Benefits to the MNC's Knowledge Base

There are several benefits in transferring knowledge across the MNC. The knowledge most frequently transferred is marketing know-how, followed by the distribution and technological know-how. However, the most valuable knowledge to HQs is the customers and competitors' market-related information, which is less transferred (Ambos et al., 2006), perhaps because it is based on tacit knowledge. However, R&D and marketing knowledge can be also considered as the one that brings more benefits to the parent company (Rabbiosi & Santangelo, 2013).

Knowledge itself influences the RKT within the MNC as this influences the degree of innovation, the level of multinationality, and the social capital, especially the internal social capital, of the MNC (Jiménez-Jiménez, Martínez-Costa, & Sanz-Valle, 2014). As such, it is more important to study the benefits of knowledge transfer than just the knowledge flows (Ambos et al., 2006).

Performance and Productivity

Another way to check the positive results of RKT is looking at the MNC's results/outcomes, for example total factor productivity, turnover, capital and employability, among other factors. By doing this, Driffield et al. (2016) concluded that the subsidiary's productivity has a positive impact on the HQs' performance.

SOLUTIONS AND RECOMMENDATIONS

MNCs compete in broad resource and product/service markets and stretch out through various countries, involving people and different ways of doing business. Knowledge is an important intangible competitive advantage that MNCs need to manage properly across the countries where they have subsidiaries. Moreover, as subsidiaries play different roles, and as countries have different factor endowments HQs have to manage not only knowledge within the corporation, but also the reverse knowledge transfer from subsidiaries to HQs.

The literature presented in this article unveils some issues and problems in the RKT processes, such as the subsidiary's age, location and entry mode and distance between corporate units in many above-mentioned dimensions.

With this in mind, this section puts forward some recommendations directed to MNC's management.

Early-created subsidiaries should receive training, so they can be quickly embedded within the MNC's modus operandi, which needs to be a continuous organizational learning culture. All subsidiaries, specially the older ones need to foster knowledge transfer capabilities and should be ready to welcome and transmit their knowledge to the new employees.

In addition, a knowledge management system should be officially created to manage the knowledge transfers, assure the frequency of communication, increase internal embeddedness, develop knowledge performance indicators and monitor them. This knowledge management system must include control, coordination and socialization mechanisms, of both personal and technological natures. Periodic electronic reports, development of communities of practice and annual summits would help subsidiaries and their key stakeholders be on the same page, thereby benefiting the MNC's overall success. The experiences' exchange between old subsidiaries, young subsidiaries and the HQs can be fruitful for the establishment of relationships and competition pertaining cultural, economic and relational distances.

The development of 'glocal' HR practices must be included, increasing the disseminative capacity of all subsidiaries and enhancing the knowledge's quantity and relevance, promoting the RKT from subsidiaries located in developing countries and increasing the market application of transferred knowledge.

Finally, expatriates must be encouraged to share their lively experiences, since they have more ability to transfer knowledge in a short-term basis. When returning, active training and experience exchange should be done, so that the MNC can take advantage of the relevance and uniqueness of the expatriates' knowledge and the expatriates' willingness to transfer knowledge.

FUTURE RESEARCH DIRECTIONS

RKT is crucial to build relevant organizational knowledge and its adequate management will certainly help MNCs to succeed overseas. Knowledge comes from all the people involved within the MNC and technologies (including social networks) can help HQs and subsidiaries to monitor what is new in which subsidiary. This would allow the development of a market, competitive and resource intelligence knowledge repositories that would enable the MNC to deal with a global mindset and an evolving-oriented culture.

Although Kogut & Mello (2017) refer that the studies using quantitative methodologies have a pre-dominant presence in this research area, due to the cultural and individual differences that may influence the results, the adoption of qualitative methodologies, such as multiple case studies and in-depth interviews, may be a sign of detailed, substantial and context-specific descriptions about knowledge transfer practices and processes, thus increasing the understanding of reverse knowledge transfer.

Finally, as knowledge and knowledge management have a pervasive effect on competitive advantage, it would be advisable to extend research on RKT and MNCs beyond the confinement of the business, management and economics arena including studies on HR management (Dobrai et al., 2012; Minbaeva & Michailova, 2004), computer science, and information management.

CONCLUSION

Within the MNCs, RKT research is becoming more and more important. Knowledge is the best source of continuous competitive advantage and subsidiaries need to be seen as centers of unique strategic knowledge, crucial for the MNC to be competitive worldwide.

Several subsidiaries' characteristics are important when studying RKTs. Subsidiaries that have more autonomy and participate actively in strategic decision making are naturally more willing and capable to transfer knowledge to the HQs. The entry mode chosen by the HQs to penetrate foreign markets may also dictate the success of RKTs, as acquired and Greenfield subsidiaries contribute to the multinational knowledge in different manners.

Generally, the larger the subsidiaries, the more knowledge they transfer. Moreover, larger subsidiaries also transfer knowledge more frequently than other types of subsidiaries. Location is a relevant fact, since it has been proven that subsidiaries from developed countries tend to take part in knowledge transfer process.

In addition, the type of subsidiary is important as not all subsidiaries behave alike in transferring knowledge. For example, regarding the degree of knowledge creation, Contributors and Innovators are among the subsidiaries that reversely transfer more knowledge. The subsidiary's external (with the market) and internal (with the HQs) embeddedness is also an important factor of influence.

Concerning the relationship between HQs and subsidiaries, the HQs' absorptive and heeding capacities, as well as the subsidiary's disseminative capacity should be improved so that the likelihood of RKT is successful. As cultural, geographical, economic and organizational distances create a barrier to overseas communication, MNCs need to deploy the use of personal and technological coordination mechanisms. However, results relating distance are not coherent, thus it is important to highlight the need to understand and explain the situational and geographical context and its implications. A good example is the research paper of Li et al. (2007), in which two different countries are compared: Finland and China. HQs may

Figure 1.

implement expatriation programs and control mechanisms (formalization and centralization) to increase, for example, the frequency of communication, which represents a positive effect on RKT. The adoption of 'glocal' HR practices might be an option for MNCs to establish an organizational learning culture globally. The practices would be similar for all the operational units. At the same time, MNCs need to respect the local learning methods in order to develop broad, plural competencies.

In spite of being more complex and tough to transfer, tacit knowledge might be more strategically relevant than explicit knowledge. With this in mind, MNCs should try to find ways to explicit the tacit knowledge. However, explicit knowledge is also beneficial to RKT.

Finally, as Ambos et al. (2006) stated, the benefits of RKTs should be highlighted, since these are the reasons MNCs perform RKT in the first place.

Figure 1 summarizes the main factors that impact RKTs within MNCs, as shown in this chapter.

KEY TERMS AND DEFINITIONS

Absorptive Capacity: An ability of a person who recognizes the value of knowledge already acquired and link that to new information and its usefulness.

Corporate Language Proficiency: Degree to which a person can speak, write, and understand the most used language within the business (mostly English).

Cultural Distance: Represents differences between people from diverse cultural backgrounds and the way it affects their relationship. Language, religion, racial or ethnic origin and traditional costumes and values are examples of factors.

Disseminative Capacity: An ability of a person who can spread the information in the best way possible for the receiver to understand it, through face to face and/or through a technological device or network.

Explicit Knowledge: A type of knowledge that is formal and systematic. It consists of the description of facts, concepts, and relationships. It is easily communicated and shared through documents, procedures, and software.

Glocal Human Resource Management: A MNC's ability to focus on the characteristics of a global organization, and also to adapt human resource practices to the local markets and/or cultural characteristics of the subsidiaries.

Heeding Capacity: HQs' ability to overcome cultural and linguistic barriers through willingness and active listening.

Multinationality: It is normally associated to firms that produce and sell goods in different countries. A degree that evaluates in how many different countries (and cities within those countries) a multinational organization establishes business relationships.

Relational Distance: Lack of personal or trust bonds between the employees within one or between two corporate units of an organization.

Tacit Knowledge: A set of as skills, ideas, and experiences that people have but are not codified. It is the type of knowledge that is complex, diffused, ingrained in the people of the organization. It is related to technical skills and know-how, but also to mental models, beliefs and perspectives.

Knowledge Harvesting Concept Paves Way for Open Innovation Initiatives

N. Raghavendra Rao

FINAIT Consultancy Services, India

INTRODUCTION

The basic functions such as production, marketing and finance continue to be the same from the day world has moved from agriculture economy to industrial economy. Business processes, procedures, methods, strategy, management thinking and approach related to basic functions have been changing. Any change such as adding to the new features to the existing products, designing a new product, changing the business processes, business models and other activities in the basic functions in an organization has to be carried out. This assignment is given to research and development department. The role of a research and development in an organization is to think of a new approach for the above activities. In case there is no research and development department in an organization, a group of executives at the instruction of the management will form as a group to carry out innovation initiative for the above activities. Their innovative approach will be based on the professional experience and knowledge (Anderson N & Costa A C, 2010). Their innovative approach will aim to be competitive in the market. In the present business scenario, it is not enough for enterprises to be competitive, but it is required to be acceptable as suppliers or service providers. Now it has become a necessary for every enterprise to think differently and follow a new approach to manage their business goals. Now critical business needs decide the type of innovation initiative is to be adopted.

In recent times open innovation initiative is gaining importance for the strategic management purposes. Now enterprises have started opening up their open innovation process and adapt their business models to benefit not only from internal but also from external ideas and knowledge. An important aspect of open innovation is that enterprises can capitalize on expanding the research and development activities by using external ideas as well as internal ideas for expanding their domestic and global markets. The open innovation approach forces enterprises to cross boundaries to get ideas from the various stakeholders (Arora, 2015).

Essence of Open Innovation

Open innovation project is knowledge intensive. It has become an imperative to collaborate in learning and sharing knowledge from inter organization networks (Denning & Dunham, 2012). The challenge of these networks is to manage and develop interpretations of the internal and external environments of enterprises. Personal contacts take place in the organizations' networks. Social groups are formed through their interactions. Creative individuals share their knowledge within the group. This leads to open innovation initiatives (Kasemsap K, 2014). Ultimately it can be said that open innovation in the business landscape is the solution to face rapid changes that are taking place in domestic and global economy.

DOI: 10.4018/978-1-7998-3473-1.ch123

Perception of Open Innovation

Open innovation concept has already been in existence in the corporate world for a long time. Many companies have been making use of this concept without it being referred as “Open Innovation”. Brain storming sessions are the classic examples for getting ideas. It may be noted that all the employees in the organizations are the participants to these sessions. In these sessions, gist of the business issue/problem is written on the board, where this session is held. Even silly ideas expressed at this session are discussed. After analyzing all the suggestions expressed at the session, the best workable solution will be accepted for solving the business issue/problem. Some enterprises follow “Suggestion Boxes” method. In this method “Suggestion Boxes” are kept at the important places in an organization. Employees are invited to write their ideas or suggestions in relevance to their business on a paper and drop it in the “Suggestion Box”. It is a general feeling that employees who are directly associated with the business processes or activities will have a better ideas to suggest (Schein & Schein, 2017).

The above two methods can be considered as an open innovation initiative. The participants under the two methods are the employees of the same organization. The employees are the main internal stake holders. In the present business scenario external stake holders are also invited to share their experience and knowledge for solving business issues of an organization. The concept of open innovation has received much importance due to the participation of external stakeholders in an organization’s business issues. Now open innovation initiatives are crossing the boundaries of an organization.

Back Ground

Many business enterprises rush into generating ideas to become more innovative before clearly identifying the problem in their enterprise. If the enterprises expect their employees to come up with ideas that would work, the employees need to know the business problems faced by their organization. The employees must have access to the information pertaining to the problems of their organization. It is the practice of many enterprises that their organization’s information is considered to be important and secret. It is meant for the top management’s view only. The environment in enterprises must be friendly instead of closed. Then only the employees will associate themselves with their organization. This would facilitate them to integrate creativity and strategic thinking. Creativity is certainly a part of innovation but innovation is much more (Tocci C L, Chesbrough H, & Piller F, 2016).

It is observed executives in enterprises are under the impression that innovation is associated with new products, new technology, and research development activity. This view is too narrow in the present business scenario. Innovation can be applied broadly across all aspects of an enterprise. They are such as existing products, services, business processes and business models (Knot, 2017).

Peter Drucker in his article on the discipline of innovation says that innovation is real work. It should be managed like any other corporate function. Further he explains that it does not mean the same as other business activities. He stresses that innovation is the work of knowing rather than doing. He argues innovative business ideas come from methodically analyzing seven areas of an opportunity. The areas are 1) Unexpected occurrences 2) In Congruities 3) Process Needs 4) Industry and Market Changes 5) Demographic Changes 6) Changes in Perception and 7) New knowledge. He groups the above areas of opportunity are under within a company or industry and outside a company in its social and intellectual environment. The first four areas fall under the group one and the balance three fall under group two. The glass is half full and the glass is half empty are the descriptions of some phenomena, but have vastly

different meanings. Changing a manager's perception of a glass is from half full to half empty opens up big innovative opportunities.

Globalization has created new trends such as market consolidation, Vertical market strategies and mergers in the business world. These trends have forced many business enterprises to adapt themselves to these new phenomena (Estrim J, 2009).

History of Innovation

Innovation has always been part of mankind. Since the discovery of fire by rubbing two stones together, human beings have been innovating. Innovation is probably the oldest known process. In other words innovation is an extension of a person's creativity. Human beings have been using their inner skills to create many new things to help mankind.

Historical Background of Knowledge Management

The concept of knowledge management is not new. The focus and approach has been changing over a period of time. One may observe from the literature on the history of information and knowledge that the basic patterns of behavior remained constant over a period of centuries concerning the role of information and knowledge (Tores, Ibarra & Arena, 2015). History provides many examples. Emperors in the olden days always surrounded themselves with advisors who were scholars first and politicians second. Roman emperors like the ancient Greeks consulted educated priests to gain an insight into the possible future. Indian Kings seemed to be concerned with creation of knowledge among people by allocating places for schools and libraries. Julius Ceaser used innovative construction methods and advancements in ammunitions to achieve military success. Napoleon made use of the advancements in artillery to defeat his opponents. Cornelius Vander Bilt had taken advantage of the advancements in rail road wheels and brakes to create vast commercial empire. J.P.Morgan made a huge fortune and revolutionized the financial system by developing modern investment banking practices. Tipu Sultan used war rocket in some of the battles he fought against the British soldiers. This earned universal fame as "Innovator of the World's first war Rocket". It was his victories against the British forces that ranked Tipu Sultan among the few Indian rulers who have defeated the British.

In the pre industrial era agriculture was the basis of nation's economy then the concentration was to learn more about farming. In the post industrial era manufacturing became the basis of nation's economy then the concentration was to learn more about manufacturing techniques. In the present globalization scenario the focus is towards adapting innovation and process speed in business enterprises. Knowledge base in a business enterprise is an extension of knowledge sharing systems. Business success lies in converting the information into knowledge. In today's business scenario the use of sophisticated knowledge base depends on the skill with which executives in business enterprises arrive at their findings from their analysis for framing strategy for their organization. Further business executives can draw insights from the large information stored in their systems. Conclusions drawn from these analyses will help the business executives to involve in innovation.

Indian and Chinese Thinking

Jugard is a colloquial Hindi word that roughly translates as "Innovative Fix" (Radjou N, Prabhu J & Ahuja S, 2012). It is an improvised solution born from ingenuity and cleverness. Jugard is quite simple. It is a

unique way of thinking and acting in response to challenges. It is the gusty art of spotting opportunities in the most adverse circumstances. Further it is making use of available resources fully improvising solutions by simple means.

Juggard is practiced by almost all Indians in their daily lives to make the most of what they have. Juggard applications include finding new uses for everyday objects such as empty soft drink or pickle bottles reused as containers for water, spices or lentils. When a truck cannot be repaired, diesel engine is removed and used as a cart. Juggard happens in an emergency situation. It is not a planned activity. Chinese believe in today's world the primary resource is knowledge and innovation. This resource comes from one's brain. If one's brain retires, then there is no more life (Sunted, 2011). The level of innovative thought will be one of the major economic drivers for China. Many global organizations have already established offices in China to capture both the creative kinds of its people and the tremendous market share.

Trends in Management Concepts

One can find from the analysis of trends in management in every decade. New concepts have been emerging. The moment it emerges, it is considered as "Next Big Thing" or "Next Important Concept". In 1950's "Brain Storming" Concept has become popular. It was considered to be a very important factor in involving the employees in business enterprises to generate new ideas. In 1960's and 1970's, sensitivity groups have played an important role in business enterprises. The group leaders of this group have been considered to be "Gurus". They would lead group managers. Then it has been practice, "Gurus" would make brief opening remarks and they would wait for response from the group managers. Then the "Gurus" would facilitate them to express and try to clarify. It was a hope that "Inner Manager" would emerge. It was expected that more research would follow on their deliberations. The era 80's was considered as the age of quality management. During this period quality control, quality circles, six sigma and other related approaches were followed for enhancing workers performance. The quality related approaches have been continuing for a long time. In the recent past, the need for knowledge management has been felt very much to face globalization secenario. In the present era the concept of "Innovation" is becoming ultimate goal of enterprises to face the complex global economy (Vint V K, 2009).

Invention, Innovation and Creativity

The terms invention and innovation are used interchangeably. Actually these are separate and distinct concepts. Invention means designing and creating something which has never been made before. The classic examples are invention of light bulb by Thomas Edison, and Invention of telephones by Alexander Graham Bell. Louis Pasteur came up with vaccines. Innovation deals with bringing in new methods and ideas resulting in required changes in an enterprise. In the present business context, innovation is taking interesting ideas and transforming them into usable solutions (Vangundy B, 2008).

Creativity can be defined as discovery of a new idea or connection (Mathur, Singh, & Ashutosh, 2013). Many ideas already exist somewhere in the World. Creativity is to identify these ideas and connect them in a new way. But innovation is much more than just identifying and connecting these creative ideas. It is about strategy and action bringing values to the enterprise through the implementation of these creative and strategic ideas. Innovation can therefore be interpreted as the profitable implementation of strategic creativity (Goel, 2016).

Example for Invention and Innovation

John Shepherd Barron reached his bank a little late and thought that why there could not be a system to get cash on the lines of chocolate vending machine. This thought gave him an idea to invent the first automatic cash dispensing machine now known as ATM. John had also thought of the four digits PIN Number. Creation of ATM can be considered as a classic example for invention and innovation. Many more features are being added to ATM by other people. Invention of ATM has given a scope for adding additional features in ATM. The enhancement of additional features can be considered as innovation (Gerard & Costa, 2013).

Types of Innovation

Innovation can be applied broadly across all aspects of an enterprise such as existing product, services, processes and business models (Prahalad C K, & Masshelkar, 2011). Innovation can be classified under three categories. They are 1) Efficiency Innovation 2) Evolutionary Innovation and 3) Revolutionary Innovation.

Efficiency Innovation

Efficiency Innovation talks about the changes in the existing processes in enterprises. The management is generally happy for small changes made in the existing processes and procedures in their organization. This approach is usually to cut costs, reduce cycle time or designing a simple format of a report to the top management of an enterprise.

Evolutionary Innovation

Evolutionary Innovation concentrates on ideas that represent something distinctly new and better. An example under this category is the introduction of internet banking. This has changed banking business from the fixed hours to banking at any hour. The other example under this type is advertisement in tabloids. Advertisements make the publishers of tabloids possible to distribute news free of charge with the revenue from the advertisements. The business models such as B2C, B2B, and B2G have been providing a scope to innovate improvements and expansion in enterprises.

Revolutionary Innovation

Revolutionary Innovation focuses on something radically new. This may change the existing structure of an enterprise and market place. McDonalds approach to fast foods changed the restaurant business. Disney's unique characters and interactive theme parks changed the entertainment business. Internet has brought a change in business scenario. It will continue to change in the industry sectors also.

Need for Innovation

The innovative spirit among the inventors is responsible for inventing the car, the telephone, television, and the internet. The world is benefited from manifestations of the innovative spirit. One may wonder what makes the need for innovation different in the present day context (Chesbrough H, 2011). Business

world is in the middle of significant transition. Three factors are playing important role in the present transition period. The three factors are information technology, the expanding world, and demanding customers.

Need for Clear Focus

The important aspect that is required in an enterprise is the type of innovation it wants to pursue (Dastur P A, Sawant S & Bawa B, 2012). There will be conflicting views among the executives in enterprises. Many times ideas suggested by the employees are not encouraged for fear of the unknown once they are presented. Enterprises generally support very small impact of efficiency innovation. It is very important at the beginning of any project to discuss the type of innovation the enterprise is expecting. Decision has to be taken in light of the available resources such as the core competencies and culture of the enterprise. Innovation momentum for an enterprise is like a snow ball. Snow ball gains in size and power as it rolls down the hills. Similarly an enterprise gains power as more and more employees adopt an innovative attitude and succeed in finding distinctly new and better ideas.

Enterprises cannot afford to depend on one person or one department to focus on the future. They need to have every employee in every area of an enterprise to be on the lookout of innovative ideas. It is the tendency of the employees to continue old and comfortable way of doing things. Sometimes it is a tough proposition for the employees to drop their emotional attachment to the way they are presently working. Enterprises need an innovation road map and detailed action plans. Innovation road map is required to enable enterprises in the creation of innovation centric organization. Innovation road map should address knowledge and skills of employees for innovation environment of an enterprise (Dyer J, Halgregeresen, & Christensen C M, 2011).

Knowledge Harvesting

The concept of knowledge harvesting is the key element in an open innovation. Knowledge harvesting is an integrated set of processes that allow the often hidden insight of human expertise in business enterprises to be captured. Then it is converted into a specific actionable know-how that can be transferred to others. The actionable know-how will be stored in an information system which will help thereby to create organizational value and enhance in decision making processes, record facts about critical decisions. Further it will facilitate to create meta knowledge about actual working adapted to changes (Lester R K, & Piore M J, 2010).

The word “Harvesting” generally applies to agriculture. It refers to the practice of increasing the yield of cultivable land. In the same way organizational databases are considered as equivalent to cultivable land. In the context of organizational environment, the employees “Wisdom” can be considered as “Manure”.

The employees’ wisdom will help the data in the system to be converted into useable information.

Case Illustration-1

3G textile mill is one of the leading textile mills in India. This textile mill has been in the business over five decades. The unique aspect of this mill is that is being managed by a management consisting of president, senior president, and vice president who belong to three different generations. Their approach and decisions are based on their experiences, business insight and education. All the three in the top management team keep updating themselves new technologies in their textile business besides keeping

them aware of new trends in information technology and market trends. They are assisted by a team of executives who have rich experience in the respective field of textile industry.

3G textile mill has been manufacturing cloth material for western and eastern counties' ladies requirements. They also manufacture shirting, and suiting materials besides producing readymade garments for men and women. They enjoyed major global market share for their products till the globalization policy followed by many countries. It is because of changing scenario in the global market, their market share is affected. Consequently their profits have been fluctuating. The top management along with their team of executives have analyzed that they have cost advantage over their competitors. They have edge over in the process technology and size of business enterprise. They have come to the conclusion, after the analysis that their weak link is in the fashion technology. They hired the services of domain experts in the field of textiles who are familiar with the tastes of people in European and Eastern counties. They expected that their guidance will help them to improve their global market share. The domain experts have their offices in Paris and Singapore.

Cloth Material

Cloth material is designed by the domain experts from their experience based on the needs of the consumer requirements such as color combination of dyes with the cotton mix. The domain experts have made use of the virtual reality concept in designing the cloth material according to the latest trends in the European and Eastern countries.

Readymade Garments

The domain experts have taken into consideration the latest trends in the fashion in the European and Eastern Countries. The domain experts designed and created garments on the basis of real world requirements of the two countries (Gallo C, 2012). Simulated versions of readymade garments are carried out in the computer systems under the cloud computing environment. The concept of virtual reality helped them to look from the real world situation. Resources in cloud computing environment have made it possible for the domain experts to create designs for the requirements of 3G textile mill.

Management Team of 3G Textile Mill

The management team along with their technical executives in India is able to view the design of cloth material and design of readymade garments on their system. They have suggested the changes wherever they felt they are required.

Social Media and 3G Textile Mill

The management team at 3G Textile Mill has realized that the market place is about brands and consumers speaking to each other. Further brands have been losing control over the kind of conversation that is taking place about the brand. The internet has moved the control of brands into consumers' hands and that is posing new challenges for brand owners. It has become a necessity for brand owners either need to have more people speaking positively about the brands or have fewer people speaking negatively. Social media plays a crucial role in both the cases. They have realized the need for exclusive social media sites for business activities.

Marketing Wing

The management team has felt that the concept of social media is to be made use of for their business. A sample cloth material and garments have been designed by the domain experts with their experience, knowledge and also with the inputs from the executives of the 3G Textiles. The concepts of virtual reality and multimedia are applied in creating a material with the different combination of colors. While designing the cloth material, the types of dyes available in the market are also kept in mind.

The marketing department of the mills has created an exclusive social media channel for the prospective customers to express their opinions of the proposed design of a cloth material and garments. The proposed design of their products is uploaded in the site. Vendors of dyes have been informed to visit the social media site to get an idea the types of dyes are to be supplied once the proposed design is finalized.

Interactions with the prospective customers on the social media site have facilitated them to understand their needs and tastes. This has helped the mills to design a cloth material and garments from the data and information from the social media site created exclusively by the marketing department (Chang W, & Taylor S A, 2016).

. This Case Illustration gives an overview of the approach followed by the textile mill to design a cloth material for ladies making use of the concepts such as virtual reality and multimedia. The feedback from the prospective customers on the social media channel facilitated them to finalize the design of the cloth for production. Further vendors who supply dyes and raw cotton are able to get the required information for supplying the materials as per the requirements of a new design. Customers' tastes are becoming more homogeneous around the globe. The feedback on social media channel facilitates to innovative approach (Chiporni D, Chiesa V, & Frattini F, 2011).

Innovative Approach

It is clear from 3G textile mill's innovative approach that new products can be designed and developed by the domain experts who are away from the Indian soil. This is because the domain experts' involvement of the process of continuous exchange of ideas among the members of virtual team dispersed across the globe. This process helps in generating alternative ideas by taking inputs from different sources and structuring through virtual reality applications. This model provides an idea for the creation of global innovative approach. It facilitates to structure the work flow by visualizing the various phases of the development of a product.

In today's knowledge rich environment, 3G textile mill has proved that enterprises can no longer afford to rely entirely on their ideas to advance their business. It may be noted that they have not restricted their innovative approach to a single path market. As a result the traditional model of innovation which has been largely internally focused or a "Closed One" has become obsolete. Emerging in its place is a new paradigm "open Innovation". This strategically leverages internal and external sources of ideas and takes them to market through multiple paths. Global enterprises can take advantage of unique knowledge and resources wherever they are located. Information and communication technology has created virtualization in activities and ways of working. The approach of 3G textile mill explains in adopting innovative approach. Further it applies the concept of "Mind Invoking" (Govindarajan, & Christrimble, 2011).

Approach in Case Illustration-1

3G textiles felt for the need for innovation. They have a clear focus in their innovative approach. They have applied revolutionary innovation method in designing and developing a product. They have involved their executives along with the domain experts in the innovative approach followed by them. They have made use of the concepts such as virtual reality, cloud computing and knowledge harvesting in their product designs. It is interesting to note that the management team consists of three different generation people. They are ready to adopt innovative approach to face the challenges in the present globalization scenario. It is apt to note the observations of Linda A H, Greg B, Emily T, & Kent L, (2014) in their book that though each of our leaders and their firms differed in key ways all leaders paid particular attention to making sure their organizations were able to collaborate, engage in discovery driven learning, and make integrative decisions. In the case of 3G Textiles the top management team, executives in their organizations, domain experts, vendors, and the prospective customers worked as a team to apply revolutionary innovation approach (Gupta P, 2009).

Case Illustration -2

Consumable products such as tooth brushes, tooth pastes, shaving brushes, and shaving creams are being manufactured by different small scale units in South India. Their products are more competitive in the rural market in South India. It is because of pricing and the features of the products are produced basically to the local needs of the people. Each unit supplies to various distributors for marketing their products. These manufacturers feel that their distributors give more importance to the reputed brands of similar products. Direct marketing to the retailers is not financially feasible to them.

Small scale manufacturing unit owners are members in a local social club. They know each other member in the club. They meet and have formal talk among themselves. They never discuss about their business. A member of the club asked the tooth brush manufacturer why his products are not available in the market. To avoid the endorsement he said that he would find out from his office. The manufacturers of the other consumable products who overheard the conversation of the tooth brush manufacturer with his friend felt that they too have similar issue. One of the small scale unit manufacturers has taken an initiative to call for an informal meeting to discuss about the issues pertaining to their products distribution.

During the informal meeting they discussed about their products and channels of distribution. Hiring a consultant to assess the market potential for their products and alternative method of distribution of their products is not financially feasible. They have realized that they do not have a database of the markets and related information about the competitor's products.

They have decided to form as a team and work together for their products. They are not competitive to each other product. Their products can be termed as family consumer products. They have decided to form as a team and work together for their products.

The team formed by them is given the responsibility of creating a database maintaining and updating it. All the units have agreed to share the cost of information and communication technology infrastructure. Their data base will contain the details of all distributors' network channels in the rural areas in South India. The team is able to collect the other competitor's product details. Their competitor's products are classified as two groups. One group is known as reputed brands and other one as less well known brands. The database will contain the details such as pricing, packing, discounts, credit limits offered by their competitors. They have decided to meet weekly once to review the progress and frame market strategy for their products. Their database will contain all the views, ideas, discussions, and decisions

at their weekly meetings. They have identified a common distributor for marketing their products. At frequent intervals by rotation each team member should visit the retailers and distributors for all their products. This approach will help them in the reduction in the marketing expenditure. Sales reports are to be updated in the common data base maintained by the team. All the units will come to know the movement of their products.

After understanding the importance of the common data base, it has been decided to change the name of the database as knowledge harvesting system for family consumer products. The team has expressed that their knowledge harvesting system will provide an opportunity for an open innovative initiative thinking.

Open Innovative Marketing Initiative

Frequent updating of information into the knowledge harvesting system has made the team members to browse the system. Their browsing the system has enabled them to analyze the data from the business and marketing perspective. They felt they have the required knowledge to innovate new ways of marketing.

They have come to know that the tooth brush for children is not manufactured by the tooth brush manufacturer. There is a good potential for this segment. Tooth paste and shaving creams are not available in an economy package. Production of the above products does not need any additional investment. The present infrastructure can be made use for the above production.

They have introduced a scheme offering their products together. Their offer such as one tooth brush is free for every purchase of a shaving brush. They have family pack containing all their products useful to a family. They have also other schemes of offering with the combination of different products. They have organized special road shows for their products in the rural parts of South India. The joint efforts of the small scale units helped them to increase their sales. After seeing the success of their innovative marketing approach has given them confidence to start joint venture among them for the production of the other related consumable products.

They have decided to use the unutilized floor space in their units for the joint venture of their business. Their units are located in the close proximity to each other unit. Different stages of production can be carried out in their units. They have already established the distributional channel of their existing products. It has become easy to make use of the existing market channels for their new products. Open innovative marketing initiative has led them to venture into the new business areas related their product group.

Approach in Case Illustration-2

A casual meeting at social club has paved a way for forming a business team. Exchange of views relating to their business issues has helped them to create a common knowledge harvesting system for their marketing issues. This system facilitated them to think in open innovative way for marketing their products jointly. The open innovative approach has given them an opportunity to get into new business ventures.

Case Illustration-3

An automobile manufacturer in India initially was manufacturing all the components required for the production of their cars. Due to the growth of their business and industrial activities, the demand for passenger cars has been increasing. The management of the automobile manufacturer has decided some

of the components required for their cars are to be outsourced. The automobile manufacturer has identified the small scale units who have the required infrastructure and technical knowledge to manufacture the components as per their specification for their cars. The small scale units have agreed to produce the components provided they are assured by the automobile manufacturer that later would provide the procurement schedule and delivery dates. Further the small scale units have to send delivery receipts along with the components sent to the automobile manufacturer. An invoice for the supplies made during a calendar month would be sent to the automobile manufacturer on the first day of the succeeding month for the payment. The procedure at the automobile manufacturer is to receive the components as per the delivery receipts and recorded in the materials inward register. The components will be tested for the quality by the quality inspection department. The components approved by the quality inspection department are taken into the stock. The rejected components with the rejection slips are given to the suppliers at the end of the month. Due to various components received from the different suppliers, the quality inspection department use to take their time for quality inspection and deciding about the approved quantity

Most of the small scale units are solely dependent on the automobile unit for the payments towards their supplies made to them. The automobile manufacturer pays for the components approved by their quality inspection department. Small scale units would find in very difficult to manage their finance. It is because the amounts received by them less than their invoice amount. This has resulted in some small scale units finding it extremely difficult to maintain their production schedule. Consequent to this the automobile manufacturer's production is affected. There used to be frequent meetings between the purchase department of the automobile manufacturer and the owners of the small scale units. There has not been any meaningful outcome from these meetings.

Solution to the Above Case Illustration

A group of executives from the departments of purchase, production, quality inspection and finance at the automobile manufacturer formed as a core team to study and find a solution for receiving the components as per their standard. Further they wanted to find a way that the small scale units would not struggle for the flow of money for their business.

They have discussed among themselves the various aspects related to the issue. After a lot of deliberations they have decided to change the procedure followed by them in their company. They have agreed to create a separate group in the quality inspection department to test the quality of the components received from the small scale units. They need to send the accepted quantity information through e-mail to the concerned small scale unit. The small scale unit could raise an invoice for the accepted quantity on the basis of the e-mail advice. The quality inspection department would send a goods accepted note to the finance department. This will be in a printed form. The idea behind a printed form is to help the finance department for relating with the copy of invoice received by them. In this process the small scale units have an option either to rectify the rejected components or to produce the additional components. This procedure has solved the issue of the small scale units. Further it has helped the automobile manufacturer to solve the bottle necks in their production schedule.

OBSERVATION

The deliberations among the stake holders of the automobile manufacturer have resulted in acceptable and working solution to the both parties. The automobile manufacturer is able to maintain their production schedule. Small scale units have also succeeded in managing their finance and also improved their quality procedures.

Generally executives in any organization confined themselves to their functional activities. Experience leads many executives to think within their functional boundaries. The core group at the automobile a manufacturer unit started thinking “Outside the Box” and forgot their functional boundaries. The core group has been triggered to rethink the way they followed the procedure in their company. This has helped them to come up within new ideas. The purpose of open innovation is to find break through solutions to the process issues.

Important Observation

The above three case illustrations facilitate executives in business enterprises to understand the importance of knowledge harvesting and open innovation initiatives in the present business scenario.

Future Trends

The future of open innovation is very bright. Adopting new methods and designing products or services will ultimately be overtaken by an open innovative approach. A new approach developed through open innovation initiative can be referred as designing or developing a new approach (DNA). DNA leads to form new strategies by enterprises for making open innovation effective in the modern business (Dwiedi, 2016).

CONCLUSION

The boundaries of the business are no longer clear. Expansion is happening in multiple new areas simultaneously. This expansion is leading to uncertainty in business, new threats from unexpected quarters and new competitions (Christensen C M, Bartman T, & Vanbeer D, 2016 September).

Effectiveness of open innovation comes from selecting specific open innovation project. There should be a clear understanding of what an enterprise wants to achieve in business and which opportunity the enterprise wishes to pursue (Rangaraju & Kennedy, 2013). Turning out lots of innovative ideas and products without a vision saps precious resources. Opportunities for enterprises come from recognizing and solving business issues that no one else has identified. But opportunities themselves are getting harder to spot and more complex to understand and exploit. There is no definite statement of the problem. Each solution reveals new aspects of the problem. Knowledge is more than book learning. But knowledge solely in a specific discipline is insufficient to bring an idea to the market place. Knowledge from many disciplines will be required. The innovator need not be a master of all things. The innovator needs to be totally aware of the knowledge associated with purposeful and effective in open innovation approach. Organizations have different priorities in developing business models under open innovation initiative. The approaches by enterprises will vary. All the management concepts when closely observed one can find open innovation element is hidden in the concept. It may be noted that every concept begins with an idea.

KEY TERMS AND DEFINITIONS

Core Team: A team consists of domain experts to perform multiple disciplinary activities.

Globalization: The process by which business starts operating on a global scale.

Innovation: This deals with bringing in new methods and ideas resulting in required changes in an enterprise.

Invention: Innovation means designing and creating something has never been made before.

Knowledge Harvesting: Knowledge harvesting is an integrated set of processes that allow the often-hidden insight of human expertise to be captured. Then it is converted into a specific actionable know-how that can be transferred to others.

Social Media: Social media use web technology to quickly disseminate knowledge and information to huge number of users. Face book, Twitter, Blog, and other similar social networking site are collectively referred to social media.

Virtual Reality: A system in which images that look like real three-dimensional objects are created by a computer system.

Information Overload

11

Tibor Koltay

Eszterhazy Karoly University, Hungary

INTRODUCTION

Even though the complex phenomenon of information overload (IO) often remains unrecognized (Badke, 2010) and is qualified to be a modern-day myth (Tidline, 1999), it is a major impediment to efficiently using information in the business world, academia and the professions both in the case of print and online (digital) documents, IO is one of the perhaps best known ‘information pathologies’ (Bawden & Robinson, 2009), thus it signalizes the existence of a dark side of information. Nonetheless, the technological and social approaches to mitigating its syndromes, i.e. the ‘bright side’ of information is also worth of attention (Koltay, 2017). This encyclopedia entry will examine both sides by describing the history, the diversity of concepts, types and sources of the multifaceted phenomenon of information overload and the ways of coping with it.

BACKGROUND: THE CONCEPT OF INFORMATION OVERLOAD

Information overload can be defined as a state in which not all inputs can be processed and utilized for varied reasons (Nelson, 1994). In other words, it occurs when potentially useful information received by someone becomes a hindrance (Bawden & Robinson, 2009), be it persons or organizations (Jackson & Farzaneh, 2012). Appearing in academia, the business word and everyday life, it affects both individuals and systems (Nelson, 1994). Information overload situations appear in activities, related to information retrieval and the organization of information, in decision and communication processes (Eppler & Mengis, 2004).

The main factors of IO are the following ones:

- The volume of information supply (the quantity of information);
- Information processing capacity;
- Information-processing requirements;
- Time requirements for processing information (available versus invested time);
- Subjective (personal) factors.

Some definitions also mention dysfunctional consequences of being overloaded that may be qualified as symptoms (effects), which are mainly related to the loss of control over information, frequently leading to suboptimal decisions, and higher time requirements for information handling, causing time delays (Eppler & Mengis, 2004). It is also associated with the feeling of being overwhelmed. In some cases, these effects can lead to a loss of job satisfaction and even damages to personal relationships or someone’s own health (Bawden & Robinson, 2009). Results of an empirical examination show that the perception of IO exist among varied age groups (Benselin & Ragsdell, 2016).

DOI: 10.4018/978-1-7998-3473-1.ch124

However, though paradoxically, information overload can provide satisfaction, because mastering it gives to many people the feeling that they are in control of something (David Johnson, 2014).

THE HISTORY OF INFORMATION OVERLOAD

While complaints about an overabundance of books date back at least as far as the sixteenth century, Ecclesiastes, one of books of the Tanakh (Hebrew Bible) originally written c. 450-180 BCE, might be the first writing to comment on the “proliferation of information as a detriment to effectiveness and efficiency” (Bawden & Robinson, 2009, p. 183).

George Simmel, a turn-of-the-century sociologist has been identified as the first commentator, who recognized the concept in its modern sense (Wurman, 2001). About the first writers mentioning information overload, there are contradictory opinions, whether it was Richard L. Meier, an American urban scholar in 1962, or the social scientist Bertram M. Gross (also from the United States) in 1964. In any case, the concept itself became a generally accepted problem in the late 1950s and early 1960s (Bawden & Robinson, 2009). In the 1970s and 1980s the focus was on IO related to the quantity of journal articles and consumer choice. Later attention shifted to email overload. Attention to IO has increased with the appearance of the Internet and World Wide Web, then with wiki systems, weblogs and mobile communications (Benselin & Ragsdell, 2016).

THE TYPES AND NATURE OF INFORMATION OVERLOAD

We can experience information overload

- in academia, impacting researchers, faculty and students;
- in business environments, impacting decision makers and other employees, as well as customers;
- in everyday life, impacting the general public (Butcher, 1998).

We can differentiate between objective and subjective IO, where the former is based on the characteristics of information, such as its amount and complexity that influence processing time. Subjective IO refers to feelings that individuals have, when confronted with information (Ji, Ha, & Sypher, 2014).

It is also necessary to tell apart the macro level of IO from its micro level. The macro level is of quantitative nature, i.e. is related to the limits of physical storage and processing capacities that present an obstacle to information access. IO at the micro level mainly depends not on the quantity of information, but is determined by its characteristics is a qualitative phenomenon. This kind of overload is essentially a failure to filter information, (Davis, 2011). Due to its qualitative nature, it also can be termed *cognitive*, *sensory*, *communication*, or *knowledge* overload (Eppler & Mengis, 2004). Some of these will appear in this encyclopedia entry in order to illustrate the diverse approaches to IO. Diversity and novelty also characterizes *data overload* that appeared in answer to the growing interest in different kinds of data and their importance, reflecting the excess of data and the similarity between data and information.

If speaking about information overload (including data overload) as an issue for professionals, we can see that it concerns varied fields. A review of literature, using the Web of Science database for the period from 1990 to 2017 found 2,469 publications on IO. The leading subject area of these publications was computer science with 56%, while the literature in engineering produced 20.5%. Other areas

present were (in descending order) business economics, information science and library science, and telecommunications (Virkus, Mandre, & Pals, 2018).

THE SOURCES OF INFORMATION OVERLOAD

The concept of information overload is associated with the notion of excess, but this is not a sufficient condition for being overloaded. Therefore, overload should be seen in comparison to some norms, which regulate what is an appropriate amount of information and which piece of information is undesirable (Himma, 2007).

Several earlier studies attributed IO to the prevalence of e-mail messages. Even a recent survey and interview study sixty one percent of 82 students from Tallinn University felt that they checked their e-mails or mobile phone messages too frequently (Virkus, Mandre, & Pals, 2018).

A case study of five organizations from the hotel industry within the hospitality sector shows that employees struggle with the excessive amount of information and data, especially in the context of digital data. Feeling overwhelmed is particularly salient if the data available is unstructured and available through third-party Internet platforms (Saxena & Lamest, 2018).

While the effect of excessive information quantity, predominately called TMI (Too Much Information) is real and undeniable, it is not the only cause of IO (Bawden & Robinson, 2009). Moreover, Neylon (2011) underlines that in an information-driven society we simply cannot have too much information. This means that besides TMI, we can name a mix of varied causes that may contribute to IO. Some of these ones are innate qualities of the information to be processed, or determined by the given task or process (that also define information processing requirements) (Eppler & Mengis, 2004).

It also makes a considerable difference if we request the given piece of information ('pull') or it was provided without being asked for ('push') (Jackson & Farzaneh, 2012). Even though search engines usually present a selection of information that is overwhelming, they do it only at the users' desire (Benselin & Ragsdell, 2016). This means that – despite of the quantity of information – it makes a difference, when information does not arrive constantly without being under the user's control (Bawden & Robinson, 2009).

A growing complexity, materializing in diverse and abundant information choices in almost all fields (Morville, 2005) is also a source of IO. The variety of networked information comes among others from a greater diversity of formats and types available, while it is delivered through a limited number of interfaces (Bawden & Robinson, 2009). Equivocality, i.e. the existence of multiple valid interpretations and variety (Bettis-Outland, 2012) and tendency to change quickly and in an unpredictable way, i.e. the volatility of information, i.e. (Davis, 2012b) also must be mentioned as sources of IO. The novelty, complexity, ambiguity and uncertainty of information, its debatable usefulness, questionable relevance or validity also may increase IO (Jackson & Farzaneh, 2012).

Besides the nature and quality of information, the cognitive style, attitudes, qualifications, and experience of information users play substantial role. They comprise not only people's capacity to process information, but refer to limited skills, or lack of motivation (Eppler & Mengis, 2004).

Information processing requirements may largely contradict to the person's processing capacity and time available negatively influence performance. Interruptions in processing and the need for multi-tasking further aggravate the situation (Jackson & Farzaneh, 2012).

The occurrence of IO can also be related to the organizational design of a company, the changes that create the need for more intensive communication and coordination, even though better organization and coordination may diminish overload. As to the influence of the tasks and processes, it can be said that

they exert more pressure on the individual if they go beyond recurring routines and when various tasks must be managed in a parallel way (Eppler & Mengis, 2004). Most of the above factors are coupled with people's general inefficiency in performing a given task (Davis, 2012a).

By its increasing complexity, the constantly evolving information landscape requires the application of *metacognitive strategies* (Walton, Pickard, & Dodd, 2018).

Metacognitive strategies are used to monitor or control our cognition and selecting the most appropriate cognitive strategy for the task we are undertaking (Quigley, Muijs, & Stringer, 2018). In a broad sense, metacognition is thinking about thinking. It can be divided into metacognitive knowledge, which is our understanding of cognition; metacognitive monitoring that takes, when we evaluate the current state of our cognition, and metacognitive control, meaning the adjustment of our cognition to the actual needs (Devers, Devers, & Oke, 2018). As demonstrated by Sannomiya and Ohtani (2015), cognitive overload inhibits metacognitive activities, though impairment is selective. Research on individual's use of metacognitive strategies during information searching underscores that planning, monitoring, and evaluating skills is of high value, because it improves search outcomes, thereby reducing the occurrence of irrelevant materials (Blummer & Kenton, 2014).

The prevalence of smartphones, social media, and online shopping induced new areas of information overload. In the present day information environment, in particular in the case of social media, the problem of quantity is aggravated by the lack of incentives to remove outdated, unused or forgotten information from the net (Brown, 2010). An example of heavy use of social media services that can be identified as source of IO can be found in responses of the Tallinn University study (Virkus, Mandre, & Pals, 2018).

The users of social media services feel boredom and fatigue as they become overwhelmed by the excessive number of sites, contacts and content (Bright, Kleiser, & Grau, 2015). One of the main reasons for this is that users cannot control their use of social media sites, due to the quick pace of information exchange (Benselin & Ragsdell, 2016) and the "always connected" communication environment (Lee, Son, & Kim, 2016). These circumstances explain, why we can say that information overload is one of the main antecedents of the social network fatigue syndrome (Shokouyar, Siadat, & Razavi, 2018). Therefore, it is not by accident that IO also can be termed *information fatigue* (Virkus, Mandre, & Pals, 2018).

In the case of online shopping, consumers experience information overload, when:

- Information, provided by online vendors is characterized by complexity and ambiguity;
- Vendors provide a number of brand alternatives;
- Consumers perceive system interface issues, related to the number of advertisements, software upgrade, requests, complex procedures, security concerns or slow access (Li, 2017).

Mobile information overload, having the basically the same causes that were described by earlier general research on information overload, is a prevalent phenomenon among smartphone users, involving distraction and impatience, induced by the TMI feeling. On the other hand, the limitations of the phones, such as uncomfortable inputting methods and small screen sizes, can also be disturbing even if relatively small amounts of information have to be processed (Feng & Agosto, 2017).

SOLUTIONS AND RECOMMENDATIONS: COPING WITH INFORMATION OVERLOAD

11

There are not only pro, but contra arguments for applying coping strategies, because we may say that our senses can not only handle a huge amount of input but enable the identification of significant patterns within it. On the other hand, we are ill-equipped to deal with the information delivered in the present-day information environment in multiple and complex forms (Bawden & Robinson, 2009).

Despite doubts, people usually are not passive when confronting IO (Eppler & Mengis, 2004), because they assume that being overloaded by information is not acceptable, neither on the individual, nor on the societal level. As a result, providers and consumers of information can apply various information management strategies to reduce information overload. This means that if IO can be positioned as a phenomenon on the dark side, while mitigating it can be qualified as an action to look on the bright side (Koltay, 2017).

Seen from a different angle, some of the strategies, applied in order to reduce IO are of technological nature, while others tackle social issues. Notwithstanding, in many cases they represent the two sides of the same coin. In this regard, it is also often discussed, whether technology is a main cause or a solution to IO. In most cases the conclusion is that it is not technology itself that causes IO but its use or misuse is responsible for it, therefore technologies are not efficient if users do not have adequate skills necessary for their use (Benselin & Ragsdell, 2016).

Technological solutions are mainly based on the idea that information overload is a result of a failure to create high quality information (Simpson & Prusak, 1995). Therefore, improving the quality of information via the proper presentation of information, materializing in its organization, selection, and format play key role in reducing IO (Jackson & Farzaneh, 2012, Blummer & Kenton, 2014). The reason for this is that the level of information processing capacity of the individual may increase, if we can improve the conciseness, consistency and comprehensibility of information on the input side of informing (Eppler & Mengis, 2004).

Among technological approaches that point to this direction, information architecture (IA) may play a distinguished role, as its main responsibility is designing, implementing and evaluating acceptable and usable information spaces (Dillon, 2002). IA is not only about surface architecture that concentrates on design issues, i.e. how information is presented and how users interact with the information system, but must be interested in content and in gaining deep understanding of information users (Brown, 2010).

For instance, slimming down website structures by removing obsolete links can not only enhance usability, but has the potential to reduce IO (Chen, 2018). Many problems, related to smartphones' limitations, mentioned above also can be solved by applying the tools of information architecture. While this is true, unfortunately, information architecture's power is generally limited, because information architects can discover IO only retrospectively and through indirect means (Davis, 2012a).

In contrast to technological solutions, social approaches offer a much broader repertoire of answers. This is especially true for the micro level of IO, propagated by people and caused by the lack of adequate filters to information or failure to apply them properly (Davis, 2011).

Most social approaches to combating IO are based on the belief that it can be mitigated by offering appropriate education, based on the critical assessment of information. Such assessment applies critical thinking, the backbone of which is the processes of analyzing, synthesizing, and evaluating information, necessary to understand and acquire knowledge (Radcliff & Wong, 2015). Reading information and assessing it critically should be applied both to information consumption and production. This requires

innovative thinking and problem solving, as well as self-management and cross-cultural interaction skills (Lee, 2013).

Pragmatic frameworks for such activities are offered by varied literacies. When speaking about them, it would be a legitimate concern to decide if there is a one-and only literacy that stands out from the multitude of new literacies, such as information literacy, data literacy, media literacy, and digital literacy. However, their development has shown different trajectories, characterized by the proliferation of concepts in this area, coupled to their complexity and change (Bawden, 2014).

The most widely known new literacy concept is *information literacy* that can be defined as the ability to think critically and make balanced judgements about any information we find and use (CILIP, 2018). This state-of-the-art understanding of the concept concerns all kinds of media.

We must refrain from explaining the similarities and differences between different literacies, except in the case of a relatively new type of literacy, i.e. *data literacy*. While in some cases appearing under different names, such as *data information literacy*, *science data literacy*, and *research data literacy*, data literacy has several close ties to information literacy. It can be defined as a set of skills and abilities related to accessing, understanding, interpreting, managing, critically evaluating and ethically using data (Koltay, 2015a).

Although not named ‘literacy’ or ‘critical approach’, managers’ behavior, found by Saxena and Lamest (2018) exemplifies possible coping strategies as it includes being selective about data sources, focusing more on qualitative data and engaging in summarizing unstructured data. This example is one of the numerous social approaches to mitigating IO that “revolve around the principle of taking control of one’s information environment” (Bawden & Robinson, 2009, p. 187). This feature is markedly present in the approach that underlines the importance of time management, because time constraints may profoundly obstruct decision making, especially if critical decisions have to be made (Hargittai, Neuman, & Curry, 2012).

Although seen from a slightly different angle, practicing slow information behavior is also connected to time. It means slowing down the pace of looking for information and consuming it. Such behavior is not only useful, but also shows characteristics of being critical against information. Slow information behavior is based on Slow Principles, exercised in many areas of life, originating in the Slow Movement. While not identical with doing something less rapidly but concerned with a carefully weighed way and a reflective attitude, as well as with judging the right speed for our behavior, this behavior is based on the belief that the present pace of information intake reduces our chances to make choices about what to consume (Poirier & Robinson, 2014).

From among the different approaches to mitigating IO, information architecture concentrates on the relationship between relatively well-defined actors, i.e. architects and their target audience, literacies operate on a more collective, societal level; applying slow principles pertains to a personal level, where the creator is less visible. No less is this true, for Personal Information Management (PIM), where the role and activities of individuals are emphasized. Focusing on the control of someone’s own environment, these individuals manage information, which is in their own possession.

Personal information management (PIM) is an activity in which an individual stores personal information items in order to retrieve them later (Bergman, 2013).

This fulfill this functions, mentioned in the above definition, PIM has to enable storing information, organizing and retrieving it using analogue and digital tools, usually by applying someone’s own, personal scheme and/or system. By origin, personal information items can be either public, or produced by people themselves, while both types can be present in the PIM environment of the same person (Jones & Maier, 2003).

Gathering personal information is accompanied by decisions to keep or discard a given piece of information. If it is judged to be useful, decisions need to be made in what format (print, electronic, or both) to keep it, where to keep it, how to structure or classify it, not forgetting about considering its relationship to other items. Positive decisions are followed by creating or organizing some sort of personal information space, where recognition and enabling retrieval should be cared for. In the case of researchers, PIM gains special weight, because most researchers ‘own’ more objects than they can remember (Bruce, Jones, & Dumais, 2004).

Keeping and discarding information, based on its critical assessment may be directed to cure the symptoms of IO.

PIM concerns both analog and digital forms of information. The analog form of PIM is still used, as people continue to take notes on paper in ordered form, usually on index cards. In the digital environment, there are other tools for organizing information. Retrieving information is possible by searching someone’s computer desktop, but in many cases it is difficult to find what someone is looking for, if it is not known or it is not a remembered object (Marshall, Bly, & Brun-Cottan, 2007). Varied citation management software products (e.g. EndNote, RefWorks or Zotero) also can be used for managing personal collections.

FURTHER RESEARCH DIRECTIONS

Since the first use of the term ‘information overload’ in the 1960s (Levy, 2008) up until the present day, neither definitions of the concept nor its effects have substantially changed. On the other hand, its causes have diversified over time with the advancement of technology. Fortunately, approaches to alleviating its symptoms also are developing constantly. This is especially true for literacies in general and for data literacy, in particular. Therefore, their development may open new ways to finding solutions to the problems of information overload, thus requires further examination.

Another objective of future research can be the investigation, directed towards understanding the relationship between multitasking and information overload (D’Arcy, Gupta, Tarafdar, & Turel, 2014).

In the areas, affected by IO, there is a considerable hype about Big Data. By its excessive volume, velocity and variety (De Mauro, Greco & Grimaldi, 2016), it may cause IO. Nonetheless, there seems to be no explicit discussion of its impact. One of the reasons for this lack can be that the Big Data phenomenon is often described in popular terms, without properly examining the complexity and expertise required for its analysis and interpretation (Borgman, 2012). Therefore, examining this aspect of IO also can be a new research direction.

CONCLUSION

Information overload remains an immense, global problem that requires solutions to reduce its effects. On the other hand, sources and frequency of IO, as well as some of the technological and social approaches, designed to reduce IO or alleviate its symptoms are present and they are evolving. From these approaches, IA activities and efforts, directed towards achieving findability serve the user, but usually are not performed by the user, will remain with us. Literacies, in contrast are a property of the individual but are based on societal qualities, will continue to offer a wide specter of solutions. Neither will not

lose its importance Personal Information Management, which is one of the conceivably most widespread approach to ease the burden of information overload.

KEY TERMS AND DEFINITIONS

Critical Assessment: A critical approach towards information that comprises critical thinking about information and critical reading of it.

Data Literacy: A set of skills and abilities based on information literacy, designed to assess critically and handle all kinds of data, but focusing on research data.

Information Architecture: Concentrates on helping information users in effectively fulfilling their information needs by creating ways that make content findable and usable.

Information Literacy: A set of skills and abilities that concerns all kinds of media and enables recognizing information need, finding the needed information, critically evaluating and using it for different purposes.

Information Overload: A set of subjective and objective difficulties, mainly originating in the amount and complexity of information available and people's inability to handle such situations.

Personal Information Management: A set of skills, coupled with analogue and digital tools, applicable for collecting and maintaining a personal collection of documents, produced either by the given person or acquired from other sources.

Slow Information Behavior: A reflective and critical way of choosing the appropriate speed of consuming and producing information.

Big Data Analytics and Mining for Knowledge Discovery

INTRODUCTION

Progresses in information science and technology have enabled the collection and generation of huge volumes of valuable data—such as streams of banking, financial, marketing, organizational, and transactional data—at a high velocity from a wide variety of rich data source in various real-life business, engineering, education, healthcare, hospitality and tourism, scientific, as well as social applications and services in government, organizations and society. These *big data* (Madden, 2012; Leung, 2015; Bellatreche et al., 2019) may be of different levels of veracities (e.g., precise data, imprecise and uncertain data) and/or of a variety of types or formats (e.g., structured data in relational databases; semi-structured data in extensible markup language (XML) or JavaScript object notation (JSON) format stored in document-oriented or graph databases; unstructured data in images, audios and videos). Embedded in the big data is implicit, previously unknown, and potentially useful information and knowledge. However, the big data come with volumes beyond the ability of commonly-used software to capture, manage, and process within a tolerable elapsed time. Hence, new forms of information science and technology—such as *big data analytics and mining for knowledge discovery*—are needed to process and analyze the big data so to as enable the enhanced decision making, insight, and process optimization. For instance, the discovery of organizational knowledge (e.g., common customer complaints, main causes of employee turnover, sets of popular merchandise items in shopping carts)—via techniques like big data analysis, statistics, and business analytics—helps reveal important patterns about an organization. This organizational knowledge helps executive and management teams of the organization to get a better understanding of the organization so that they could make better use of human resources and technology, focus more on education and growth, keep customers top of mind, and further improve quality of services and products. To a further extent, the discovery of organizational knowledge and its subsequent actions help the organization to meet goals, gain competitive advantage, and ultimately ensure sustainability, organizational growth and development.

Over the past two decades, algorithms have been proposed for various big data analytics, mining and knowledge discovery—including clustering (which groups similar data together), classification (which categorizes groups of similar data), outlier detection (which identifies anomalies), and frequent pattern mining (which discovers interesting knowledge in the forms of frequently occurring sets of merchandise items or events). Many of these algorithms use the *MapReduce* model—which mines the search space with distributed or parallel computing (Shim, 2012). Among different big data analytics and mining tasks, this chapter focuses on applying the MapReduce model to big (organizational) data for the discovery of frequent patterns.

DOI: 10.4018/978-1-7998-3473-1.ch125

BACKGROUND

Since the introduction of the research problem of *frequent pattern mining* (Agrawal, Imieliński, & Swami, 1993), numerous algorithms have been proposed (Hipp, Güntzer, & Nakhaeizadeh, 2000; Ullman, 2000; Ceglar & Roddick, 2006; Aggarwal, Bhuiyan, & Al Hasan, 2014; Leung et al., 2017c). Notable ones include the classical Apriori algorithm (Agrawal & Srikant, 1994) and its variants such as the Partition algorithm (Savasere, Omiecinski, & Navathe, 1995). The Apriori algorithm uses a level-wise breadth-first bottom-up approach with a candidate generate-and-test paradigm to mine frequent patterns from transactional databases of precise data. The Partition algorithm divides the databases into several partitions and applies the Apriori algorithm to each partition to obtain patterns that are locally frequent in the partition. As being locally frequent is a necessary condition for a pattern to be globally frequent, these locally frequent patterns are tested to see if they are globally frequent in the databases. To avoid the candidate generate-and-test paradigm, the tree-based FP-growth algorithm (Han, Pei, & Yin, 2000) was proposed. It uses a depth-first pattern-growth (i.e., divide-and-conquer) approach to mine frequent patterns using a tree structure that captures the contents of the databases. Specifically, the algorithm recursively extracts appropriate tree paths to form projected databases containing relevant transactions and to discover frequent patterns from these projected databases.

In various real-life business, engineering, healthcare, scientific, and social applications and services in modern organizations and society, the available data are not necessarily *precise* but *imprecise or uncertain* (Leung, 2014; Leung, MacKinnon, & Tanbeer, 2014; Cheng et al., 2019; Rahman, Ahmed, & Leung, 2019; Titarenko et al., 2019). Examples include sensor data and privacy-preserving data (Leung et al., 2018; Chen et al., 2019; Leung, Braun, & Cuzzocrea, 2019; Li & Xu, 2019). Over the past decade, several algorithms have been proposed to mine and analyze these uncertain data. The tree-based UF-growth algorithm (Leung, Mateo, & Brajczuk, 2008) is an example.

With huge volumes of big data, it is not unusual for users to have some phenomenon in mind. For example, a manager in an organization is interested in some promotional items. Hence, it would be more desirable if data mining algorithms return only those patterns containing the promotional items rather than returning all frequent patterns, out of which many may be uninteresting to the manager. It leads to *constrained mining*, in which users can express their interests by specifying constraints and the mining algorithm can reduce the computational effort by focusing on mining those patterns that are interesting to the users.

Besides the aforementioned algorithms discover frequent patterns *in serial*, there are also *parallel and distributed* frequent pattern mining algorithms (Zaki, 1999). For example, the Count Distribution algorithm (Agrawal & Shafer, 1996) is a parallelization of the Apriori algorithm. It divides transactional databases of precise data and assigns them to parallel processors. Each processor counts the frequency of patterns assigned to it and exchanges this frequency information with other processors. This counting and information exchange process is repeated for each pass/database scan.

As we are moving into the new era of big data, more efficient mining algorithms are needed because these data are wide varieties of valuable data of different veracities with volumes beyond the ability of commonly-used algorithms for mining and analyzing within a tolerable elapsed time. To handle big data, researchers proposed the use of the *MapReduce programming model*.

BIG DATA ANALYTICS AND MINING FOR FREQUENT PATTERNS

The MapReduce Programming Model

MapReduce (Dean & Ghemawat, 2004, 2010) is a high-level programming model for processing huge volumes of data. It uses parallel and distributed computing on large clusters or grids of nodes (i.e., commodity machines), which consist of a master node and multiple worker nodes. As implied by its name, MapReduce involves two key functions:

1. the “map” function, and
2. the “reduce” function.

To solve a problem using MapReduce, the master node reads and divides input big data into several partitions (sub-problems), and then assigns them to different worker nodes. Each worker node executes the *map function* on each partition (sub-problem). The map function takes a pair of $\langle \text{key}, \text{value} \rangle$ and returns a list of $\langle \text{key}, \text{value} \rangle$ pairs as an intermediate result:

- map: $\langle \text{key}_1, \text{value}_1 \rangle \mapsto \text{list of } \langle \text{key}_2, \text{value}_2 \rangle$,

where:

1. key_1 & key_2 are keys in the same or different domains, and
2. value_1 & value_2 are the corresponding values in some domains.

The pairs in the list of $\langle \text{key}, \text{value} \rangle$ pairs for this intermediate result are then shuffled and sorted. Each worker node then executes the *reduce function* on:

1. a single key from this intermediate result, and
2. the list of all values that appear with this key in the intermediate result.

The reduce function “reduces”—by combining, aggregating, summarizing, filtering, and/or transforming—the list of values associated with a given key (for all k keys) in worker nodes and returns a single (aggregated or summarized) value:

- reduce: $\langle \text{key}_2, \text{list of value}_2 \rangle \mapsto \text{a single value}_3$,

where:

1. key_2 is a key in some domains, and
2. value_2 & value_3 are the corresponding values in some domains.

Besides a single value_3 , alternative output could be a list of $\langle \text{key}_3, \text{value}_3 \rangle$ -pairs or a list of value_3 (where key_3 is a key in some domains).

By using the MapReduce model, users only need to focus on (and specify) the map and reduce functions, without worrying about implementation details for partitioning the input data, scheduling and

executing the program across multiple machines, handling machine failures, or managing inter-machine communication.

Earlier works on MapReduce mainly focused on data processing in big databases (Dean & Ghemawat, 2004, 2010) or some big data mining tasks other than frequent pattern mining. Examples of big data processing with MapReduce include the construction of inverted indexes, the evaluation of queries involving joins or selection, the elimination of duplicates, text processing tasks (Lin & Dyer, 2010; Jiang & Leung, 2015) like the word counting of documents, and the processing of data cubes (Lee & Kim, 2016). Examples of big data mining with MapReduce include classification (Arias, Gámez, & Puerta, 2017), clustering and outlier detection (Ceccarello, Pietracaprina & Pucci, 2019).

Apriori-Based MapReduce Algorithms: SPC, FPC, and DPC

To mine frequent patterns from big databases of precise data with MapReduce, Lin, Lee, & Hsueh (2012) proposed three algorithms—namely, the Single Pass Counting (SPC), Fixed Passes Combined-counting (FPC), and Dynamic Passes Combined-counting (DPC) algorithms—based on both the Apriori and the Count Distribution algorithms. SPC first divides the databases into partitions, and then executes map and reduce functions in each pass k to generate candidate k -itemsets (i.e., candidate patterns each consisting of k items) and count their support/frequency. More specifically, SPC executes the following map and reduce functions in Pass 1:

- map: $\langle \text{ID of transaction } t_j \in \text{partition } P_i, \text{ contents of } t_j \rangle \mapsto \text{list of } \langle \text{item } x \in t_j, 1 \rangle$, and
- reduce: $\langle x, \text{list of 1's} \rangle \mapsto \text{list of } \langle \text{frequent 1-itemset } \{x\}, \text{sup}(\{x\}) = \text{sum of 1's in the list for } x \rangle$.

Here, the worker node corresponding to each partition P_i of the big databases executes the map function by outputting $\langle x, 1 \rangle$ (which represents the support of candidate 1-itemset $\{x\}$ in $t_j = 1$) for every item x in transaction $t_j \in P_i$. After grouping all the 1's for each x to form $\langle x, \text{list of 1's} \rangle$, the reduce function is then executed by summing all the 1's in the list for each x to compute its support $\text{sup}(\{x\})$, and outputting $\langle \{x\}, \text{sup}(\{x\}) \rangle$ (which represents a frequent 1-itemset $\{x\}$ and its frequency) if $\text{sup}(\{x\}) \geq$ a user-specific *minsup* threshold.

In each subsequent pass $k \geq 2$, SPC generates candidate k -itemsets from frequent $(k-1)$ -itemsets. The worker node corresponding to each partition P_i then outputs $\langle X, 1 \rangle$ for every candidate k -itemset X that exists in some transaction $t_j \in P_i$. Afterwards, the reduce function sums all the 1's for each X to compute its support $\text{sup}(X)$, and output $\langle X, \text{sup}(X) \rangle$ (which represents a frequent k -itemset X and its frequency) if $\text{sup}(X) \geq \text{minsup}$. In other words, SPC executes the following map and reduce functions in Pass k (for every $k \geq 2$):

- map: $\langle \text{ID of } t_j \in P_i, \text{ contents of } t_j \rangle \mapsto \text{list of } \langle \text{candidate } k\text{-itemset } X \subseteq t_j, 1 \rangle$, and
- reduce: $\langle X, \text{list of 1's} \rangle \mapsto \text{list of } \langle \text{frequent } k\text{-itemset } X, \text{sup}(X) = \text{sum of 1's in the list for } X \rangle$.

The three algorithms (SPC, FPC and DPC) are similar except that both FPC and DPC apply the *pass bundling* technique to reduce the number of passes/database scans in each P_i when generating candidate itemsets (for Pass $k \geq 3$). For instance, FPC statistically bundles a fixed number of passes (e.g., three passes) to generate all candidate k -, $(k+1)$ -, and $(k+2)$ -itemsets from frequent $(k-1)$ -itemsets. In contrast, DPC dynamically bundles several passes (depending on the number of generated candidates in these bundled passes).

Partition-Based MapReduce Algorithm

On the one hand, the use of the pass bundling technique reduces the number of passes/database scans in each partition P_i . On the other hand, the Apriori-based SPC, FPC and DPC algorithms still require multiple passes/database scans when mining frequent patterns from big data. In contrast, the MapReduce version of the Partition algorithm—presented by Leskovec, Rajaraman, & Ullman (2020)—requires only two passes/database scans. Hence, the Partition-based MapReduce algorithm uses two sets of “map” and “reduce” functions. Specifically, the master node reads and divides big databases of precise data into partitions. The worker node corresponding to each partition P_i then outputs $\langle X, 1 \rangle$ for every candidate pattern X (of any cardinality) that exists in some transaction $t_j \in P_i$. The reduce function then sums all the 1’s for each X to find patterns that are locally frequent in P_i . Taking the union of these locally frequent patterns forms global candidate patterns. To summarize, the first set of “map” and “reduce” functions can be expressed as follows:

- map: $\langle \text{ID of transaction } t_j \in P_i, \text{ contents of } t_j \rangle \mapsto \text{list of } \langle \text{itemset } X \subseteq t_j, 1 \rangle$, and
- reduce: $\langle X, \text{list of 1's} \rangle \mapsto \text{list of } \langle \text{locally frequent itemset } X, \text{NULL} \rangle$.

Afterwards, the worker node corresponding to each partition P_i outputs $\langle X, 1 \rangle$ for every global candidate pattern X that exists in some transaction $t_j \in P_i$. Then, the reduce function sums all the 1’s for each X to compute its support $\text{sup}(X)$, and outputs $\langle X, \text{sup}(X) \rangle$ (which represents a globally frequent pattern X and its frequency) if $\text{sup}(X) \geq \text{minsup}$. To summarize, the second set of “map” and “reduce” functions can be expressed as follows:

- map: $\langle \text{ID of } t_j \in P_i, \text{ contents of } t_j \rangle \mapsto \text{list of } \langle \text{global candidate pattern } X \subseteq t_j, 1 \rangle$, and
- reduce: $\langle X, \text{list of 1's} \rangle \mapsto \text{list of } \langle \text{globally frequent pattern } X, \text{sup}(X) \rangle$.

Tree-Based MapReduce Algorithm for Precise Data: PFP

Given that tree-based algorithms avoid the candidate generate-and-test paradigm of Apriori-based algorithms, Li et al. (2008) proposed the Parallel FP-growth (PFP) algorithm for query recommendation. PFP uses MapReduce to parallelize the tree-based FP-growth algorithm by first reading and dividing big databases of precise data into several partitions. The worker node corresponding to each partition P_i then outputs $\langle \{x\}, 1 \rangle$ for every item x in transaction $t_j \in P_i$. The reduce function then sums all the 1’s for each x to compute its support $\text{sup}(\{x\})$, and outputs $\langle \{x\}, \text{sup}(\{x\}) \rangle$ (which represents a frequent 1-itemset $\{x\}$ and its frequency) if $\text{sup}(\{x\}) \geq \text{minsup}$. In other words, PFP first executes the following set of “map” and “reduce” functions:

- map: $\langle \text{ID of transaction } t_j \in \text{database partition } P_i, \text{ contents of } t_j \rangle \mapsto \text{list of } \langle \text{item } x \in t_j, 1 \rangle$, and
- reduce: $\langle x, \text{list of 1's} \rangle \mapsto \text{list of } \langle \text{frequent 1-itemset } \{x\}, \text{sup}(\{x\}) = \text{sum of 1's in the list for } x \rangle$.

Afterwards, PFP reads the big databases a second time to form an $\{x\}$ -projected database (i.e., a collection of transactions containing x) for each item x in the list produced from the first reduce function (i.e., for each frequent 1-itemset $\{x\}$). The worker node corresponding to each projected database then performs the following:

1. builds appropriate local FP-trees (based on the projected database assigned to the node) to mine frequent k -itemsets (for $k \geq 2$), and
2. outputs $\langle X, \text{sup}(X) \rangle$ (which represents a frequent k -itemset X and its frequency) if $\text{sup}(X) \geq \text{minsup}$.

To summarize, PFP executes the second set of “map” and “reduce” functions as follows:

- map: $\langle \text{ID of transaction } t_j \in P_i, \text{ contents of } t_j \rangle \mapsto \text{list of } \langle \{x\}, \{x\}\text{-projected database} \rangle$, and
- reduce: $\langle \{x\}, \{x\}\text{-projected database} \rangle \mapsto \text{list of } \langle \text{frequent itemset } X, \text{sup}(X) \rangle$.

As PFP was designed for query recommendation, it usually takes a third set of “map” and “reduce” functions to aggregate and rank the list of frequent itemsets for the top-K frequent patterns to facilitate recommendations.

Tree-Based MapReduce Algorithm for Uncertain Data: MR-growth

Characteristics of big data can be described by at least 5Vs: volume, value, velocity, variety, and veracity. Among the 5Vs, veracity focuses on the quality of data (e.g., precision, uncertainty, messiness, or trustworthiness of data). In many real-life applications, available data can be *uncertain*. Uncertainty of the data may partially be caused by various factors such as imprecision or limitation of measuring instruments, as well as intentional blurring of data for privacy-preserving data. Hence, in these applications, users may be uncertain about the presence or absence of some merchandise items or events. For example, a manager may highly suspect (but cannot guarantee) that a customer is interested in certain products without explicitly asking the customer. The uncertainty of such suspicion can be expressed in terms of existential probability. Hence, to handle uncertain data, each item x in the transaction t_j is associated with an existential probability $P(x, t_j)$ expressing the likelihood of the presence of that item or event. With this notion, each item in a transactional database of precise data can be viewed as an item with a 100% likelihood of being present in the transaction.

When using probabilistic-based mining with the “possible world” interpretation (Leung, 2014), a pattern is considered *frequent* if its expected support is no less than the user-specified *minsup* threshold. When items within a pattern X are independent, the *expected support* of X in the database can be computed by summing (over all transactions) the product (of existential probabilities within X):

$$\text{expSup}(X) = \sum_{t_j} \left(\prod_{x \in X} P(x, t_j) \right), \text{ where } P(x, t_j) \text{ is the existential probability of item } x \text{ in transaction } t_j.$$

Leung & Hayduk (2013) presented the MR-growth algorithm, which uses MapReduce to mine frequent patterns from *uncertain* data in a tree-based pattern-growth fashion for big data mining. Again, MR-growth uses two sets of the “map” and “reduce” functions. Specifically, the master node reads and divides uncertain data into partitions. The worker node corresponding to each partition P_i then outputs $\langle \{x\}, P(x, t_j) \rangle$ for every item x in transaction $t_j \in P_i$. Note that, unlike the map functions for the aforementioned algorithms (which output $\langle \{x\}, 1 \rangle$ for representing the actual support of x in $t_j = 1$, i.e., x appears 1 time in t_j), the map function for MR-growth outputs $\langle \{x\}, P(x, t_j) \rangle$ (where $P(x, t_j)$ indicates the expected support of x in t_j , which means x has a probability of $P(x, t_j)$ to appear in t_j):

- map: $\langle \text{ID of transaction } t_j \in \text{database partition } P_i, \text{ contents of } t_j \rangle \mapsto \text{list of } \langle \text{item } x \in t_j, P(x, t_j) \rangle$.

Then, the reduce function sums all the $P(x, t_j)$'s for each x to compute its expected support $expSup(\{x\})$, and outputs $\langle \{x\}, expSup(\{x\}) \rangle$ (representing a frequent 1-itemset $\{x\}$ and its expected support) if $expSup(\{x\}) \geq minsup$:

- reduce: $\langle x, \text{list of } P(x, t_j)\text{'s} \rangle \mapsto \text{list of } \langle \text{frequent 1-itemset } \{x\}, expSup(\{x\}) \rangle$,

where $expSup(\{x\}) = \text{sum of } P(x, t_j) \text{ in the list for } x$. Notice that, when handling precise data, the actual support of $\{x\}$ is its frequency. In contrast, when handling uncertain data, the expected support of $\{x\}$ may not be the same as its frequency. For instance, consider an item b with existential probability of 0.9 that appears only in transaction t_1 . Its expected support may be higher than item c that appears seven times but with an existential probability of 0.1 in each appearance. Then, $expSup(\{b\}) = 0.9 > 0.7 = expSup(\{c\})$.

Afterwards, MR-growth rereads the big databases to form an $\{x\}$ -projected database (i.e., a collection of transactions containing x) for each item x in the list produced from the first reduce function (i.e., for each frequent 1-itemset x). The worker node corresponding to each projected database then performs the following:

1. builds appropriate local UF-trees (based on the projected database assigned to the node) to mine frequent k -itemsets (for $k \geq 2$), and
2. outputs $\langle X, expSup(X) \rangle$ (which represents a frequent k -itemset X and its expected support) if $expSup(X) \geq minsup$.

To summarize, MR-growth executes the second set of “map” and “reduce” functions as follows:

- map: $\langle \text{ID of transaction } t_j \in P_i, \text{contents of } t_j \rangle \mapsto \text{list of } \langle \{x\}, \{x\}\text{-projected database} \rangle$, and
- reduce: $\langle \{x\}, \{x\}\text{-projected database} \rangle \mapsto \text{list of } \langle \text{frequent itemset } X, expSup(X) \rangle$.

Constraint-Based MapReduce Algorithm: BigAnt and BigSAM

When mining and analyzing huge-volume big data, it is not uncommon that users may be interested in only some subsets of these big data in many real-life situations. This leads to *constraint-based mining* (Bonchi, 2009; Leung, 2009; Leung, 2018a), with which users can focus the mining on certain subsets of the big data by freely specifying some constraints to express their interest. For example, users can express their interests in finding a collection X of merchandise items having a total price of less than \$100 by specifying a constraint “ $\text{sum}(X.Price) < \$100$ ”. Similarly users can also express their interests in finding a set Y of branches with a minimum GPS coordinate (latitude) of 49°N by specifying a constraint “ $\text{min}(Y.GPSCoordinate) = 49^\circ\text{N}$ ”.

To handle these constraints and to focus the mining on those subsets of big data that are interesting to users, Leung & Jiang (2014) proposed the BigAnt algorithm to handle the user-specified anti-monotonic constraints by exploring the anti-monotonicity of the constraints, which states that “if a pattern satisfies an anti-monotonic constraint, then so do all its subsets”. In other words, if a pattern violates the anti-monotonic constraints, it can be pruned as any of its supersets is guaranteed to violate the constraints. For instance, if $\text{sum}(Z.Price) \geq \100 for some pattern Z , then $\text{sum}(Z'.Price) \geq \100 for any superset Z' of Z . So, the BigAnt algorithm also uses two sets of the “map” and “reduce” functions. The master node reads and divides uncertain data into partitions. The worker node corresponding to each partition

P_i then performs constraint checking and outputs $\langle \{x\}, P(x, t_j) \rangle$ for every *valid* item x in transaction $t_j \in P_i$ (when $\{x\}$ satisfies the constraints):

- map: $\langle \text{ID of transaction } t_j \in \text{partition } P_i, \text{contents of } t_j \rangle \mapsto \text{list of } \langle \text{valid item } x \in t_j, P(x, t_j) \rangle$.

Then, the reduce function sums all the $P(x, t_j)$'s for each valid x to compute its expected support $\text{expSup}(\{x\})$, and outputs $\langle \{x\}, \text{expSup}(\{x\}) \rangle$ (representing a valid frequent 1-itemset $\{x\}$ and its expected support) if $\text{expSup}(\{x\}) \geq \text{minsup}$:

- reduce: $\langle \text{valid } x, \text{list of } P(x, t_j)\text{'s} \rangle \mapsto \text{list of } \langle \text{valid frequent 1-itemset } \{x\}, \text{expSup}(\{x\}) \rangle$,

where $\text{expSup}(\{x\}) = \text{sum of } P(x, t_j) \text{ in the list for } x$. Afterwards, BigAnt rereads the big databases to form an $\{x\}$ -projected database (i.e., a collection of transactions containing x) for each *valid* item x in the list produced from the first reduce function (i.e., for each valid frequent 1-itemset x). The worker node corresponding to each projected database then performs the following:

1. builds appropriate local UF-trees (based on the projected database assigned to the node) to mine frequent k -itemsets (for $k \geq 2$), (ii) performs constraint checking to find valid ones from these mined frequent k -itemsets, and (iii) outputs $\langle \text{valid } X, \text{expSup}(X) \rangle$ (which represents a valid frequent k -itemset X and its expected support) if $\text{expSup}(X) \geq \text{minsup}$ and X is valid with respect to the user-specified constraints. To summarize, BigAnt executes the second set of “map” and “reduce” functions as follows:
 - map: $\langle \text{ID of transaction } t_j \in P_i, \text{contents of } t_j \rangle \mapsto \text{list of } \langle \text{valid } \{x\}, \{x\}\text{-projected database} \rangle$, and
 - reduce: $\langle \text{valid } \{x\}, \{x\}\text{-projected database} \rangle \mapsto \text{list of } \langle \text{valid frequent itemset } X, \text{expSup}(X) \rangle$.

Note that BigAnt pushes the user-specified anti-monotonic constraints into the big data mining process so that it directly discovers frequent patterns that satisfy the constraints.

To a further extent, Jiang, Leung, & MacKinnon (2014) proposed the BigSAM algorithm to explore additional property of some anti-monotonic constraints. Specifically, BigSAM explores the succinctness of the constraints, which reveals that all and only those itemsets satisfying the succinct anti-monotonic (SAM) constraints can be explicitly and precisely generated using only individual items that satisfy the SAM constraints. For instance, any set Y of branches with $\min(Y.GPSCoordinate) = 49^\circ\text{N}$ must consist of only branches with GPS coordinate of 49°N . Hence, the BigSAM only needs to perform constraint checking in the first—but not the second—map function.

FUTURE RESEARCH DIRECTIONS

Besides the MapReduce model in Apache Hadoop, alternative approaches include the use of Apache Spark (which relies on the concept of resilient distributed dataset), edge computing, and fog computing (Zaharia et al., 2010; Garcia Lopez et al., 2015; Yi et al., 2015). Hence, a logic future research direction is to adapt and perform *big data analytics and mining for knowledge discovery* (e.g., constrained

or unconstrained frequent patterns about an organization) in *Spark, edges, or fogs* (Leung et al., 2017b; Sarumi, Leung, & Adetunmbi, 2018; Braun et al., 2019).

Due to the popularity of Web-based communities and social networking sites, huge volumes of big social media data (including those Facebook, Instagram and Twitter data about an organization) are available. Embedded in these big data are rich sets of meaningful knowledge about the social networks (e.g., social networks within an organization, among different organizations). Hence, a second future research direction is to apply *social media mining and social network analysis* (Leung, Medina, & Tanbeer, 2013; Xu & Li, 2013; Leung et al., 2016; Jiang et al., 2018; Leung, 2018b) to social media data for discovery of rich sets of meaningful knowledge from these big data.

Many existing big data mining algorithms return the mined results in a textual form—e.g., a *textual list* of all (constrained or unconstrained) frequent patterns. As “a picture is worth a thousand words”, visual representation of the mining results is usually easier to comprehend for users than its equivalent textual representation. Thus, it is desirable to show the mining results interactively by applying the concepts of visual analytics. As such, to enhance user experience in exploring big data, a third future research direction is to incorporate *visual analytics and interactive technologies* (Zhang, Segall, & Cao, 2011; Leung et al., 2017a; Jentner & Keim, 2019; Leung & Zhang, 2019) into big data mining so that the (constrained or unconstrained) frequent patterns mined from big data are returned to the users in visual forms.

CONCLUSION

Big data analytics and mining aims to discover implicit, previously unknown, and potentially useful information and knowledge from big databases that contain huge volumes of valuable veracious data collected or generated at a high velocity from a wide variety of data sources. Among different big data mining tasks, this chapter focuses on *big data analytics and mining for knowledge discovery*. By relying on the MapReduce programming model, researchers only need to specify the “map” and “reduce” functions to discover frequent patterns from:

1. big databases of precise data in a breadth-first manner (e.g., by using the SPC, FPC, and DPC algorithms) or in a depth-first manner (e.g., by using the PFP algorithm), and/or
2. big databases of uncertain data (e.g., by using the MR-growth algorithm).

Such a big data analytic and mining process can be sped up (e.g., by using the BigAnt and BigSAM algorithms, which focus the mining according to the user-specified constraints that express the user interests). The resulting (constrained or unconstrained) frequent patterns mined from big data provide users (e.g., executive and management teams of an organization) with new insights and a sound understanding of users’ patterns about the organization. Such knowledge is useful in many real-life information science and technology, as well as organizational, applications.

KEY TERMS AND DEFINITIONS

Anti-Monotonic Constraint: A constraint C such that, if an itemset S satisfying C, then any subset of S also satisfies C.

Big Data: High-velocity, valuable, and/or multi-variety data with volumes beyond the ability of commonly-used software to capture, manage, and process within a tolerable elapsed time. These Big data necessitate new forms of processing to deliver high veracity (& low vulnerability) and to enable enhanced decision making, insight, knowledge discovery, and process optimization.

Data Mining: Non-trivial extraction of implicit, previously unknown and potentially useful information from data.

Frequent Pattern (or Frequent Itemset): An itemset or a pattern with its actual support (or expected support) exceeds or equals the user-specified minimum support threshold.

Frequent Pattern Mining: A search and analysis of huge volumes of valuable data for implicit, previously unknown, and potentially useful patterns consisting of frequently co-occurring events or objects. It helps discover frequently co-located trade fairs and frequently purchased bundles of merchandise items.

Itemset: A set of items.

MapReduce: A high-level programming model, which uses the “map” and “reduce” functions, for processing huge volumes of data.

Succinct Constraint: A constraint C such that all itemsets satisfying C can be expressed in terms of powersets of a fixed number of succinct sets using the set union and/or set difference operators. A succinct set is an itemset, in which items are selected from the domain using the usual Structured Query

Language (SQL) selection operator. In simple terms, a constraint C is succinct meaning that all and only those itemsets satisfying C can be explicitly and precisely generated using some precise “formula”.

Strategies for Increasing Knowledge Translation of Evidence-Based Practice in Athletic Training

INTRODUCTION

The field of health care needs to change in order to address challenges such as rising health care costs, aging populations and the need to treat increasing numbers of people with chronic health conditions. All of this must be accomplished while reducing costs and maintaining quality of care. Health care professionals are being tasked with facilitating this change. Like many other health care professions, athletic training has turned to evidence-based practice to assure that athletic trainers are trained to deliver the highest quality of care in the most efficient way to their patients. The transition to integrating evidence-based practice will be challenging and will require a massive diffusion of innovation throughout the field of athletic training.

Athletic trainers (ATs) are defined as “health care professionals who collaborate with physicians. The services provided by ATs comprise prevention, emergency care, clinical diagnosis, therapeutic intervention and rehabilitation of injuries and medical conditions. ATs work under the direction of physicians, as prescribed by state licensure statutes” (Profile of athletic trainers, 2014, para. 1). The profession of athletic training is constantly growing, and athletic trainers can be found in many different settings including high schools, colleges, working with the athletic teams, the military, and workplaces. Despite many employment opportunities, some people in the health care industry are unfamiliar with the responsibilities of the AT and it is apparent that athletic training as a profession is still lagging behind other allied health professions (Hankemeier & Van Lunen, 2013a).

BACKGROUND

The National Athletic Trainers' Association (NATA) introduced the use of evidence-based practice (EBP) in both the education of new ATs, and in the clinical setting with athletic trainers already working in the field (Hankemeier & Van Lunen, 2013; Hankemeier et al., 2013; McCarty Hankemeier, Walter, Newton, & Van Lunen, 2013; Welch, Van Lunen, & Hankemeier, 2014b). There are many benefits to increasing the use of evidence-based medicine (EBM). A benefit frequently discussed is improving both the image and recognition of athletic trainers as health care professionals and not personal trainers, physical education teachers, or the people carrying water bottles on the sideline of games. Other benefits to using EBM

DOI: 10.4018/978-1-7998-3473-1.ch126

include improving the care provided to the patients and justifying third party reimbursement (McCarthy et al., 2013; Welch et al., 2014a).

Using EBP can be broken down into five steps as shown by Sackett et al. (1996). These steps include: defining clinically relevant questions, searching for the best evidence, critically appraising the evidence, applying the evidence, and evaluating how effective evidence-based medicine was when put to use. While these steps seem relatively simple when written out, most athletic training clinicians are not using EBP in their current treatment practice, but 98% of them were found to believe that it is important for the credibility of the profession (McCarty et al., 2013). Hankemeier et al. (2013b) showed that clinicians had a lower perceived importance score and a lower knowledge score when compared with post-professional educators. ATs who work in athletic training education programs have more exposure to the notion of EBP and therefore are more knowledgeable about the importance of EBP than individuals that only work in clinical settings.

Since EBP is very new to the field of athletic training, practicing clinicians that are not recent graduates likely did not learn about EBP in the educational curriculum and would not be familiar with it unless the individual took initiative to learn the process independently. In a study completed by Hankemeier and Van Lunen (2013a) less than 20% of the surveyed clinicians received any form of EBP training. Based on the information provided in this survey, very few clinicians have been trained to use EBP. These clinicians with no background in using the five steps would need some training in order to be able to effectively integrate EBP into daily clinical practice.

Disseminating knowledge about EBP to ATs is essential in this transition. Continuing education (CE) is an important method for educating athletic training clinicians on what EBP is and how to use. In order for CE to be truly effective, athletic trainers need to understand what modes are best for presenting this information to promote long term knowledge retention and knowledge translation. Popular ways that CE is presented is through online learning, in person lectures, discussions, hands on demonstrations, and mixed mode learning. Studying modes individually for these gains or comparing one type of CE with another could help to advance understanding of how EBP should be presented to maximize an increase in knowledge and use.

Distance education, e-learning, computer mediated, web-based, and online instruction are terms used to describe education delivered through computer-based technologies. Whatever term is chosen, such computer-based technologies are essential components of the preparation and continuing education of health professionals. One of the most frequently used modes of CE, particularly for learning EBP, is online learning. Web-based learning has become very popular due to its flexibility and ease. This type of learning can be done from anywhere and completed at the convenience of the individual taking the course (Militello, Gance-Cleveland, Aldrich, & Kamal, 2014).

Allied health care tends to use three models of online learning and instruction: blended learning, online learning, and continuing education (Stewart & Wright, 2004). Blended learning includes both face to face and online learning and instruction. Online learning is learning and instruction that is completely web-based. Continuing education for health professionals is offered in both blended and online formats. In fact, most health-related disciplines are using a combination of online and face-to-face learning in their programs.

From a theoretical standpoint, characteristics of an effective online learning experience have been outlined. Reeves and Reeves (2008) provided 10 dimensions to be considered when designing, implementing and evaluating an online class in health and social work. The model they described for health and social work education included 10 dimensions of interactive teaching and learning: (1) pedagogical philosophy; (2) learning theory; (3) goal orientation; (4) task orientation; (5) source of motivation; (6)

teacher role; (7) metacognitive support; (8) collaborative learning support; (9) cultural sensitivity; and (10) structural flexibility. In the discussion of developing online learning formats, best practices often discussed include attention to instructor and student interaction, application of active learning techniques, providing prompt feedback, and attending to diverse ways of learning. While the aforementioned guidelines make sense, they have not been vetted through research. This brings us to the next questions of whether web-based instruction can be as effective as face-to-face education. The answer is that we really do not know how effective face-to-face education is, because comprehensive assessment is rarely conducted of student learning for specific courses. Many factors play a role (i.e., faculty training and course design) in the effectiveness of any course. Most health professionals rely heavily on technology in their practice and thus, it seems appropriate for technology to play a role in the education of future health professionals. In fact, Hollis and Madill stated (2006), “Evidence suggests that blending combinations of technologies with computer mediated learning enhances interaction and could address the higher order learning needs of professional programs such as occupational therapy”(p.61).

Through a review of research focused on computer-enhanced classroom-based teaching, online courses, online degree programs, and online continuing professional education, Hollis and Madill (2006) recommended that both online and face-to-face teaching and learning opportunities accommodate all types of students and faculty. Hollis and Madill (2006) emphasized the use of multiple technologies to enhance interaction between students, and between students and instructors. However, to optimize the effectiveness of online learning, they suggested appropriate preparation and support is required for both students and faculty. Again, these suggestions make sense, but also must be vetted through research designed to assess effective online learning experiences.

How is blended and online learning and education being used in health professions? Konin (2004) discussed how to enhance clinical education, like athletic training, through the use of web-based programs. Like most health professionals, education and training includes some type of fieldwork, or internship placement. Information and assessments for clinical instructors can be delivered electronically through an online course management system such as Blackboard. Face-to-face class formats can be enriched through the availability of a multitude of supplemental online materials.

A study was completed with nursing clinical preceptors who worked with undergraduate nursing students. In this study the preceptors took part in a series of online CE course objectives. These objectives were geared toward the roles and expectations of a clinical preceptor. The results showed that there was a statistically significant gain of knowledge between the pre-test and post-test, showing that knowledge was gained from online learning (Zahner, Tipple, Rather, & Schendzielos, 2009). While this study showed that online learning can increase knowledge, it did not compare online learning with traditional learning methods such as live lectures.

There is research that has been done that compares online learning with traditional live lectures. One study completed by Phillips (2015) investigated the effects of teaching a lesson online versus the traditional in person lecture class. This study was completed using a class in a pharmacy program. Students were randomly assigned to either the control group of traditional lectures, or the experimental group of active online learning. The experimental group performed higher on a multiple choice quiz given immediately after the lesson, but there was no significant difference on the final exam scores between groups. The experimental group did express that the online class was enjoyable and felt that it should be used in conjunction with traditional lectures, but should not replace lectures altogether.

Online learning and instruction is also essential to the continuing education of health-related professionals. Williams (2006) conducted a meta-analysis of 25 studies assessing achievement in distance education in allied health and found that distance education is as effective as face-to-face instruction.

Student achievement outcomes were positively correlated with work experience and professional knowledge. Outcomes were also better for distance education experiences that included multiple learning and instructional strategies including, but not limited to, interaction and introspection.

Continuing education for ATs is offered in many different forms including taking college courses, publishing papers, presenting at conferences, attending in person meetings or education seminars, and online learning (Board of Certification, 2016). Studies have shown that online CE is frequently used because of the cost effectiveness and the ease of completing it individually (Armstrong & Weidner, 2011). There have been two reporting periods that required athletic trainers to complete CE in an evidence-based practice category. During this period, ATs could choose from many different online options. These were typically formatted with a lesson that ended in a quiz to test knowledge. Passing the quiz was necessary for receiving the continuing education units. A study was completed by Welch et al. (2014a) that looked at the web-based modules pertaining to EBP.

In this study, there was an experimental group that had access to the continuing education learning modules, and a control group that did not. Both groups were given a pretest and a posttest to assess knowledge. The experimental group did significantly better than both their own pretest and the control group's scores on the pretest and the posttest. Learning was achieved in this study, but only short team knowledge gain was investigated. Whether this knowledge was retained in the long term from the online learning modules has not yet been concluded.

The experimental group in the previous study was also interviewed on their perceptions of evidence-based practice following the intervention. Overall, the response was positive with the individuals all feeling that they had learned from the modules and had a better understanding of the concepts of EBP and how to use it (Welch et al., 2014b). However, the clinicians reported that the modules did not cause a change in clinical practice and that although they learned they did not change the way they made treatment decisions. Other qualitative studies have been done regarding the attitudes toward EBP education. A topic that was emphasized was the need for constant repetition and increased exposure to evidence-based practice. These participants felt that the more exposure one has to EBP, the more comfortable they will become with it and the more likely they will become to use it (Welch et al., 2014c). A recent study by Keeley et al. (2016) found that participants felt that EBP was important, but overall they had not used EBP concepts at all in the eight weeks prior to completing the survey. The importance of EBP and short-term knowledge gain seem to be occurring, but there is still a gap between putting that knowledge to practice.

More recent research, following the requirement of EBP for continuing education has also been conducted. A study by Keely et al. (2016) surveyed athletic trainers regarding their knowledge and use of EBP following continuing education. This study found that despite an increase in knowledge that is being attributed to the continuing education, and an understanding of why EBP is important for the profession, there is little increase in use. Furthermore, research has shown that the barriers that were being presented by clinicians as hindering use, are still being presented currently (Manspeaker & Hankemeier, 2017). This is considered significant because despite the increase in continuing education, and the emphasis being placed on EBP in the field of athletic training, clinicians are not finding ways to overcome those barriers and meaningfully use EBP (Manspeaker & Hankemeier, 2017).

The reason that EBP is such a hot topic in the world of health care is to improve clinical outcomes, decrease cost, and increase patient satisfaction. To effectively implement EBP into athletic training, the athletic trainers must be using what they are learning through CE (Hankemeier & Van Lunen, 2013; Welch et al., 2014a; Welch et al., 2014b). More research needs to be done that helps to understand whether online, traditional, or a mixed mode of CE is most effective for knowledge gain and clinical use. Research designed to measure how well an individual is learning and whether that person is retaining the

knowledge could help make adjustments to the current situation regarding EBP. Comparing different ways of receiving the knowledge for effectiveness would also help to promote meaningful learning and knowledge translation. The addition of EBP to continuing education requirements is still relatively new, and it is likely that this will not be perfect on the first attempt. Continuing to understand the best ways to increase the translation of knowledge in athletic training could help the profession to successfully incorporate EBP into daily practice.

Some studies have been completed that investigate the notion of using a mixed mode method of learning. This type of CE would include different methods of learning such as combining web-based learning with an in-person discussion, or hands on demonstration that compliments what was previously learned (Militello et al., 2014). The idea that mixing a passive lecture whether online or in person with an active discussion or demonstration works well with the idea that individuals learn differently. Furthermore, reinforcing a topic often promotes long term retention, comprehension, and may increase the chance that it will be implemented into clinical use (Schreiber, Perry, Downey, & Williamson, 2013; Zahner, et al., 2009).

A particular study that utilized a more comprehensive and multifaceted approach was completed by Schreiber et al. (2013). This study used a course that was geared for physical therapist (PTs) and met on three separate occasions in conjunction with an online community used to foster discussion. During the in-person meetings, there were lectures, hands on demonstrations, and time to talk about successes and barriers to implementing the clinical change learned. In the final session, all PTs were required to discuss how they had already used what was learned in the previous courses in the clinical setting with patients. They also needed to describe an EBP activity that they had undertaken in the clinical setting. This study showed that the participants enjoyed this mixed methods learning and showed improvement in knowledge and practice behaviors such as supporting colleagues' use of interventions and tests and measures that were related to the course content.

Studies are showing that multifaceted learning increases knowledge and the translation of knowledge into clinical practice (Schreiber et al., 2013; Zahner et al., 2009). In order for change to truly occur in the field of athletic training more research needs to be completed that investigates how effective the current CE learning methods are. Short term knowledge gain is not enough to truly make a change. Whether long term knowledge gain is occurring is also important. If an individual is forgetting the course content immediately following the course then the information is not being relayed effectively (Phillips, 2015). This information must be something that the AT can comprehend and remember after a period of time. Even more importantly, however, is the idea of translating this knowledge in to clinical practice.

FUTURE RESEARCH DIRECTIONS

Understanding whether knowledge translation is occurring by looking at the knowledge to action framework for future research may be beneficial. There are several models for looking at knowledge to action, with a model by Graham et al. (2006), frequently used in allied health professions. The Knowledge to Action (KTA) process is a multidirectional process where knowledge is created and then developed to allow information to be better understood and used by healthcare professionals (Graham et al., 2006). This framework is divided into two parts, the knowledge creation funnel, and the action cycle. Through the knowledge creation funnel, new information is created and refined in order to be disseminated to the intended targets (Graham et al., 2006). The action cycle around the funnel helps to identify steps that can be used in order for the information to be spread and used widely. This begins with identifying the problem, and understanding the gaps (Graham et al., 2006). Athletic training has begun to take steps

to identify problems with EBP use, but understanding why there is an increase in knowledge and not a change in behavior is important to truly diffuse EBP into the profession. The next steps involve adapting the knowledge and assessing barriers. Barriers have been addressed in many studies (Manspeaker & Hankemeier, 2017; McCarty et al., 2013). The next steps include implementing interventions based on the problems and barriers, monitoring knowledge use, evaluating outcomes, and sustaining knowledge use (Graham et al., 2006).

The profession of athletic training is currently in the process of monitoring knowledge use, and evaluating outcomes based on the continuing education that is being provided to AT clinicians. The KTA framework is cyclical and multidirectional meaning that the process can go forward or backward, and information is constantly being evaluated. One method that has been shown to be effective in physical therapy that could warrant more research within the field of athletic training is the use of knowledge brokers (Glegg & Hoens, 2016). The idea of a knowledge broker (KBs) stems from knowledge translation and frameworks such as KTA. KBs are viewed as humans who facilitate knowledge sharing between groups such as researchers and clinicians (Glegg & Hoens, 2016). They are used to bridge the gap between evidence and practice (Hoens, Reid, & Camp, 2013). Physical therapy as a profession has been implementing this role with some success in increasing knowledge by fostering relationships with clinicians and building trust (Hoens, Reid, & Camp, 2013).

Athletic training should begin to look into whether the addition of KBs would be beneficial to the profession to help promote a more widespread use of EBP when making clinical decisions. Clinicians have discussed the importance of mentors when learning about and using EBP, and KBs can facilitate that mentorship through online relationships. Using the internet allows the KBs to reach a wide net of clinicians, and allows the clinicians to connect with the experts in an asynchronous fashion that may be more convenient the busy schedules. Using the KTA framework, and incorporating trusted KBs may help to bridge the knowledge to action gap that is being seen following the incorporation of EBP into continuing education (Keeley et al., 2016; Manspeaker & Hankemeier, 2017).

CONCLUSION

A major transition is occurring to achieve the implementation of EBP throughout the field of AT. To date, there have been two reporting periods that required ten of their fifty CEUs in an EBP category. This was the first time that athletic trainers needed a portion of CEUs to come from an EBP section. The goal is that this will familiarize all ATs with EBP in hopes that it will begin to be used more. However, research is showing that despite an increase in knowledge, there are still barriers, and little increase in use (Keeley et al., 2016). Changing the way online continuing education is presented and completed by ATs may increase comprehension and understanding of EBP. This understanding may lead to using it in clinical practice. Using the KTA process to evaluate barriers, and provide strategies to improve translation may help (Graham et al., 2006). The use of KBs in the field of physical therapy has been seen to help disseminate information and provide clinicians with support when implementing new ideas (Hoens, Reid, & Camp, 2013). One major complaint for using EBP in the clinic is a lack of comfort with how to use it (Hankemeier & Van Lunen, 2013a). Increasing frequency of exposure may help to make clinicians more comfortable with how to use EBP causing a change in practice. While there will no doubt be challenges associated with the implementation of EBP in athletic training, the use of online learning and investigating whether KBs could provide a much needed mentorship in an online setting may ease the transition for athletic trainers, managers, and organizations.

KEY TERMS AND DEFINITIONS

Allied Health: The segment of the workforce that delivers services involving the identification, evaluation and prevention of diseases and disorders; dietary and nutrition services; and rehabilitation and health systems management.

Athletic Trainers (ATs): Healthcare professionals who collaborate with physicians to provide prevention, emergency care, clinical diagnosis, therapeutic intervention and rehabilitation of injuries and medical conditions (Profile of athletic trainers, 2014, para. 1).

Continuing Education: Education provided for adults after they have left the formal education system, consisting typically of short or part-time courses.

Evidence-Based Practice: Evidence-based medicine is the conscientious, explicit, and judicious use of current best evidence in making decisions about the care of individual patients (Sackett et al., 1996).

Knowledge Broker: Individuals who work to bridge the gap between researchers and users (Hoens, Reid, & Camp, 2013).

Knowledge Translation: A dynamic and iterative process that includes synthesis, dissemination, exchange and ethically-sound application of knowledge to improve the health of patients, provide more effective health services and products, and strengthen the health care system (Graham et al., 2006).

National Athletic Trainers' Association (NATA): A professional membership association serving certified athletic trainers and others who support the athletic training profession in the United States.

Transitions: Change processes that involve a beginning, middle, and an end.

Management Science

Management Tools: From Complexity Reduction to Complexity Creation

Mazri Chabane

INERIS, France

INTRODUCTION

Anticipate, decide and control are the three structuring pillars of everyday management activities (Moisdon, 1997). Regardless of the operating field or organization structure, the management tools deployed to support these activities are expected to display two key characteristics. First, they need to vehicle a formal rationality (Weber, 1978), i.e. the results or orientations privileged by the tool are to be interpreted as the reflect of objective and well-structured calculations. Second, they allow managers to circumvent their limited rationality by providing meaningful syntheses that encompass a set of parameters or dimensions which would not have been approachable through cognitive capabilities alone. With respect to these expectations, it seems fair to state that management tools are first and foremost perceived as reducers of organizational complexity.

It is therefore unsurprising that organizations confronted by unprecedented competition, rapidly-shifting environments, and strengthened governance structures rely more and more heavily on such tools in order to adapt to their context and demonstrate accountability to a variety of stakeholders (authorities, partners, shareholders, clients, and even the public at large).

However, such a vision does not sustain a serious reflexive approach on the way in which management tools are used on an everyday basis. Indeed, by shedding light on the appropriation of management tools and the associated strategies deployed by the users thereof, assorted literature on management tools sociology as well as organizational behavior have provided us with the prerequisite hindsight to criticize what now can be assumed as a naive vision of management. Consequently, the analysis of management tools' life cycle - from conception to effective deployment and potential obsolescence - reveals how they may be at the source of a chain of human and organizational reactions, which may lead to unintended consequences and the emergence of new behaviors. Simply said, we're speaking here of complexity.

This chapter will first introduce the reader to the literature that provided, through theoretical and empirical approaches, the seeds to grow a new vision of management tools that goes beyond their supposed rationalization impact. With this background in mind, the following section describes two mechanisms through which organizational complexity is directly linked to the introduction of a new management tool. In order to do so, two distinct real case studies focused on performance indicators (PIs) in the field of industrial safety are presented. Largely deployed as a means of organizational control, PIs have spread in organizations thanks to their supposed ability to provide synthesis that directly support action. Focusing on this kind of tools should therefore reveal mechanisms of interest to a large sample of managers and researchers.

Finally, future developments are suggested, especially regarding the ability of exploiting the description of complexity mechanisms in the management tool design phase so to prevent their occurrence.

Comparatively to existing literature, this work goes beyond the observation of empirical facts resulting from the introduction of management tools to describe the underlying mechanisms at play and

DOI: 10.4018/978-1-7998-3473-1.ch127

relating them to existing concepts already made available by management science. In doing so, this work contributes to:

- provide additional empirical evidence on the need in management science to pay higher attention to the way our tools are appropriated and modified by organizations and vice versa;
- a better formalization of complexity creation mechanisms due to the introduction of management tools;
- endow managers with elements of attention to be considered at various stages of management tools life cycle (diagnosis, design and implementation) to confine the potential chain of negative reactions out of which emerges organizational complexity;
- Remind that complexity creation is inherent to management tools deployment and remains a valuable source of organizational knowledge.

BACKGROUND

Management science has flourished at the intersection of various disciplines: mathematics, sociology, psychology, philosophy, etc. In parallel, the increased specialization and segmentation of organizations has resulted in management approaches being equally specialized and autonomous. Given this context, it is unsurprising to witness the cohabitation of a large range of management trends and schools of thought the epistemic grounds of which are yet to be homogenized (Pfeffer, 1993) (Van Maanen, 1995).

Management tools are good tracers of this background, as they bear with them clear representations of the variety and evolving scientific grounds on which they rest. This starts from the very definition of this concept. A positivist-oriented definition would consider management tools as satisfactory representations of reality (Dumez, 2008), on which managers may rely in order to anticipate and act on organizational dynamics. Resulting orientations are seen as the vehicles of an objective rationality that should impose itself on users whose roles are limited to (i) providing the required inputs for the tool to operate, and (ii) apply orientations or decisions resulting therefrom (Chiapello & Gilbert, 2019). In so doing, management tools are expected to act as organizational stabilizers thanks to the compliance and even standardization of its members' actions and decisions. A very widespread trend of thought and practices that heavily relies on this philosophy is Operations Research (Ackoff, 1979) and the cybernetic approaches of organizational control (Otley, 1983). This vision, combined with rapidly-increased computational capabilities, has shaped the representation of management tools as complexity reducers (Berry, 1983)

In practice, these hypotheses have been proven limited both in terms of philosophical structure and practical applications. A short account of the main criticism is provided in the following:

- Game theory (Von Neumann & Morgenstern, 1944) allowed economics to put on the map the option of inter-organizational cooperation to achieve better results than individual optimizations. The opportunity of constant rationalization and the seeking of local optimums therefore appears, at least in some circumstances, as under-achieving compared to the anticipation of other stakeholders' moves and the design of adapted cooperation strategies.
- Human relation theory (Damachi, 1978) has stressed the importance of interactions in shaping organizational performance. It revealed the extent to which motivation, leadership and commit-

ment to shared values act as strong determinants of organizational performance, regardless of the management tools deployed.

- Behavioral theory¹ has shed light on actors' strategies within organizations when confronted with various stimulus, including the introduction of new management tools. Excessive rationalization through continuous monitoring combined with incentives and rewards systems, for instance, appeared to bear important unintentional and highly prejudicial consequences. Enlightening examples can be found in New Public Management (NPM) literature where the introduction of market-like approaches to management has led, in some cases, to public services favoring the satisfaction of performance indicators to the detriment of service quality; or to develop the systemic cheating and manipulation of data, thereby making such figures totally misleading for decision-makers (Rouse, 1993) (PASC, 2003).
- The sociology of organizations has clearly highlighted the systematic tendency for management tools design to carry out important reductions in organizational complexity (Chiapello & Gilbert, 2019). Consequently, organizations may experience the emergence of unintended consequences due to a lack of communication between tools or misinterpretations of their results.
- Decision theory also has its fair share of critics, especially the 'garbage can model' (Cohen, March, & Olsen, 1972) that puts at the forefront the concept of organizational anarchies to describe the inconsistency of decision-makers' preferences, their lack of understanding of an organization's processes, and the volatility of decision-making structures in which members' interests and influences vary over time. This depiction of organizations offers a stark contrast with the image of rationalization machines as assumed in the vision described above.

From such criticism a new vision of management tools emerged, whereby stronger priority is given to the complexity of the social and political dynamics that accompany the deployment of such tools in organizations. Such a vision starts with the redefinition of management tools as *artefacts which, thanks to the mobilization of one or several management techniques, provides managers with the ability to pursue their objectives in a given context* (Gilbert, 1998). Three keywords merit our attention here. First, *artefact* is used to remind that management tools are collective human constructs the validity scope of which should be questioned. Second, the term *technique* is directly linked to the third *context* so as to highlight their interdependence. The relevance of techniques used to build a management tool are to be questioned with respect to the social context in which implemented. The evolution of social context implies the revision of a tool's application scope.

With respect to this vision, additional efforts to highlight and describe the cognitive and social consequences of deploying management tools have come to light. Two such developments appear enlightening with respect to this chapter's objectives:

- First, the status of management tools has moved from objective prescribers of rationality to that of *rational myths* (Hatchuel, 2000). The term *rational* is used here to recognize the ability of management tools to vehicle a rationality that can be traced and revised within reflexive procedures. However, this term is combined with *myth* to emphasize the limited character of this rationality due to the reductions and simplifications that always occur when management tools and technologies are conceived and implemented.
- Given this new status, the finality of management tools is no longer to prescribe behaviors, but rather, more modestly, to create new opportunities for collective learning (Hatchuel, 2000). Dumez

(2008) follows this path further to distinguish three configurations in which management tools can achieve such an objective:

- i. when used as a means to investigate the organization's formal and informal functioning;
- ii. when used to pilot organizational change, including reorganizations or developments in new markets;
- iii. Finally, as a means to investigate uncertainties through forecast and foresight approaches (for instance).

This epistemic and methodological journey has allowed management science research to explore new areas, amongst which the analysis of management tools as complexity creators should be further investigated.

Management Tools as Complexity Creators: Two Illustrative Mechanisms and Associated Cases

Despite the still diverging literature on the epistemic grounds of complexity science (Chu, Strand, & Fjelland, 2003), it is widely acknowledged that the term refers to systems the components of which are highly connected, autonomous, interacting in a non-linear fashion, and coevolving in order to ensure the system's survival through adaptation mechanisms (Richardson & Cilliers, 2011) (Zarboutis & Wright, 2006). As a direct result, new and unpredicted system states may emerge (Holland, 1998).

Organizations have been characterized as 'complex systems' since the 1960s (Anderson, 1999). This has resulted in numerous descriptive and prescriptive theories and models, amongst which organizational design (Galbraith, 1982), cybernetics (Ashby, 1956) and Complex Adaptive Systems (Gell-Mann, 1994) have had a large echo in organization theory. This chapter will more modestly discuss how the introduction of new management tools may trigger the complex mechanisms described as the development of new and unexpected interactions, leading to the emergence of new representations or relations in an organization.

The mechanisms of complexity creation to be further discussed rely on an action research approach in the industrial safety sector. More precisely, two contexts are presented whereby the introduction of new safety indicators - intended as rationalizing mechanisms to control hazardous sociotechnical systems - have resulted in unforeseen yet highly-informative observations. These observations will be analyzed through various management science models in order to evaluate the extent to which such observations may be representative of repeatable mechanisms of complexity creation. In so doing, it is not expected to provide the reader with an exhaustive description of the mechanisms through which management tools' implementation may trigger a chain of complex reactions. However, the mechanisms described in this chapter can be generalized as they refer to repeatable patterns which description can be performed through existing concepts and models already described in management science.

According to the above, the reader may first find some elements relating to the specific context of industrial safety and safety performance indicators, before discussing in more length how the introduction of these tools has triggered complexity in organizations.

Process Safety and Safety Performance Indicators

Process safety refers to the detection, evaluation and management of the threats posed by high-risk industrial activities, the consequences of an accident at which may impact beyond the workplace and even the plant. Explosions, fires and toxic releases are examples of physical consequences that process

safety strives to avoid, or minimize the impact of which in the event of occurrence. Bhopal (1984), Chernobyl (1986) and more recently Deepwater Horizon (2010) are vivid examples of wide-scale failures in industrial safety approaches.

Industrial accidents have long been recognized as resulting from a combination of events, the roots of which may be found in technological, human and managerial inputs (Reason, 1997). This has naturally led to industrial systems being defined as sociotechnical (Emery & Marek, 1962) (Eason, 2008) in the sense that these three inputs are constantly interacting to move organizations closer or further from accidents.

Accordingly, a central theme of process safety management is the ability of organizations to continually monitor how a set of predefined factors² evolve, and to consequently act either by reinforcing positive dynamics or detecting and correcting negative ones (Hollnagel, Wears, & Braithwaite, 2015).

Performance indicators can be defined as synthetic information aimed at orienting actions. In terms of safety, SPIs³ or KPIs⁴ are widely used by the industry as a means to control their systems (CCPS, 2011) through a classical cybernetic control loop. Accordingly, these are thought to provide a satisfactory representation of reality that leads to rational decisions with regards to deployed corrections and adaptations. Such an approach is therefore a genuine exemplification of the first paradigm of management tools, as described in the previous section.

We will go in the followings through two case studies out of which two distinct mechanisms of complexity creation will be described and discussed.

Case 1: You can Never Change Just one Thing

This first intervention has been carried out at plant A that wants to monitor and optimize maintenance intervention delays in a highly hazardous part of its production process. The following contextual specificities have proven to be of particular importance for our demonstration.

- The plant used to be part of a larger industrial installation, the activities of which were split before being sold to two companies (Plant A and B). At the operational level, the two plants maintained strong ties both physically (sharing utilities) and organizationally (shared subcontracting). Plant A subcontracted maintenance to Plant B which then, for cost reasons, subcontracted it to external companies.
- This cascade subcontracting structure was organized as follows: the maintenance department collects daily requests for intervention from plants A and B. These requests are discussed at the morning meeting with representatives of the two plants, and priorities are defined according to various factors including criticality of intervention and available resources.
- Available resources, expressed as the number of intervention hours/year, are defined contractually and renegotiated every year between plant A and B on the one side, and Plant B and the contractors on the other side.

Given this context, Plant A's *Environment, Health and Safety Department* (EHS) requested the development of one or several indicators to monitor the effects of cascade subcontracting, due to the feeling that intervention delays were increasing. However, they needed "numbers" to prove it, and consequently ask for a renegotiation in favor of increasing available resources in next maintenance contracts.

Thanks to electronic traceability, intervention requests, deliverance of work permits, and the issuing of intervention reports were all dated to allow for the measurement of the *mean delay* between requests and the effective completion of maintenance work, as well as its *variance* to detect peak loads.

If the design of this KPI was straightforward, its implementation has been a more troubled story. First, the monitoring of trends using past data provided the expected “numbers” to justify increased maintenance resources. So management consequently decided to (i) increase the annual maintenance budget, and (ii) further specify prioritization rules in order to reduce intervention delays for safety critical installations.

This first set of reactions was welcomed by the EHS department, whose initial objectives behind this intervention appeared to have been satisfied. However, the new prioritization rules have slowly but surely eroded delays of some interventions considered as less safety critical but more important with respect to production constraints. Consequently, a decrease in production system availability has quickly raised flags - leading to tension between production and safety objectives. If accident investigations on several occasions have emphasized how production optimization can be conducted to the detriment of safety constraints (Graham, et al., 2011) (Jiang & Probst, 2015) (Zohar, 2010), the tension observed here is the direct result of the introduction of a new KPI. Following this, a second round of discussions included representatives from the production department and production workshop first line managers. The discussion soon raised the issue of the dynamic and ever-changing balance between safety and production. Recognizing the dynamic character of this balance puts aside the static option of fixing prioritization rules, and puts at the forefront the experience and competence of first line managers in finding appropriate tradeoffs between these two dimensions. Accordingly, prioritization rules have been replaced by new organizational arrangements where the daily maintenance meeting includes first line managers as well as the EHS departments from sites A and B.

This abbreviated history of organizations A and B illustrates one key mechanism of complexity creation as being the non-separability of knowledge and relations (Hatchuel, 2000). Indeed, organizations can be defined as schemes of interactions between knowledge and relations. A snapshot of organizations provides a representation of the interactions allowed through hierarchical structure to process available knowledge at a given time. Accordingly, the capacity of each actor in an organization to reach out for internal or external interactions is constrained by this predefined structure. However, as soon as new knowledge is introduced, its processing requires the creation of new relations inside or outside the organization, leading to the modification of the interaction scheme either by introducing new interactions or by modifying existing ones. This new set of interactions is fertile ground for the emergence of new knowledge and opportunities, which once again lead to a new round of interaction modifications.

Returning to our first case, the introduction of the new KPI, or more generally a new management tool, is the formalization of new knowledge the consequences of which lead to the generation of a new set of interactions between production and EHS. These interactions modified organizational knowledge by recognizing the unsuitable character of static rules, and the need to rely on workshop first line managers to define maintenance priorities. In turn, this new knowledge led to a new set of interactions where first line managers are included in daily maintenance meetings (Fig.1).

The dynamics of this cycle is of course conditioned by the ability of the organization to acknowledge informal interactions, and its willingness to accept structural modifications so as to adapt to its internal as well as environmental changes.

Accordingly, this non-separability of knowledge and interactions can be seen both as an opportunity for organizations to constantly adapt to the impacts of internal and external dynamics, and also as a source of complexity, since every change may modify the subtle balance between interactions and knowledge.

Figure 1. Revision cycle of interactions and knowledge illustrated by the case 1 example

Case 2: There is no High Architect of Rationalization

This second case describes an intervention in a worldwide reinsurance company, which is interested in developing a framework for the detection of new or emerging risks. An emerging risk is a new risk or a familiar one that becomes apparent in new or unfamiliar conditions (IRGC, 2010) (Mazri, 2017).

As risk is the very essence of the insurance business, detecting emerging risks and acting on the obsolescence of older risks is a key activity for insurers, as it allows new insurance products to be developed that fit clients' evolving risk profiles and retires older products that are no longer profitable.

Accordingly, an emerging risk unit has been established with the objective of investigating societal and technological dynamics that may lead to new risks emerging or older ones disappearing. Based on these investigations, the unit was expected to provide the headquarters with emerging risks candidates for which foresight capabilities highlighted the high possibility for them to trigger demands for new insurance products. The unit's business model was quite straightforward: the more emerging risks candidates integrating the portfolio of insurance products, the more successful the unit.

The unit started working with the objective of "selling" emerging risk candidates to headquarters, which in turn, assign them to risk portfolio managers in other departments. When a new risk is assigned to a department's portfolio, it is expected to trigger a process through which an insurance product is designed - with respect to technical and market constraints - so as to make it financially profitable as soon as possible. In this case, profitability was evaluated through a classic three colors model: *green* for very profitable, *orange* for low levels of profitability, and *red* for non-profitable. Every department's success was assessed according to its ability to place a maximum of insurance products in the green zone according to a predefined set of financial ratios.

Quite quickly, conflicts between the objectives assigned to the emerging risks unit and those of other departments came to light. If the emerging risk unit was pushed towards providing a maximum number of emerging risks candidates, other departments were eager to minimize the inclusion of new risks in their portfolio for two reasons. First, when a new risk is assigned to a department portfolio, it is expected to remain a few months in the unprofitable area. This lag time is necessary to tailor an insurance product

economically and technically to reach the market and win customers. However, some emerging risks may require more time, as they rely on long-term societal and technological developments. Second, developing an insurance product for emerging risks remains a bet. The high-level of uncertainties surrounding their emergence process makes it plausible for risks to emerge much later, in a different form, or never emerge at all. Accordingly, the risks taken by the company to develop an insurance product are transferred to departments, which may find themselves carrying a “deadlift”⁵. A final key element of the case’s backdrop is the formal link established between department profitability and the financial bonuses annually attributed at the individual level. In other words, every emerging risk assigned to a business unit becomes a risk of decreasing the financial bonuses of its members.

This second case illustrates how complexity may result from the design and deployment of separate management tools, which promote rationalities that are local and potentially conflicting finally leading to a *conflict of objectivation*. Two recurrent mechanisms that go far beyond the example provided above lay behind this type of conflicts:

- First, the local character of objectivation in management tools is inherited from their design and implementation. Hatchuel and Weil (1992) distinguish three descriptive dimensions that may be used to understand the forms of simplifications adopted when designing any management tool. The first dimension is the *management philosophy* conveyed by the tool. This term refers to the set of objects and objectives targeted by the rationalization effort. For instance, Taylor (1919) expected scientific management to improve production efficiency through the division of labor, whereas decision aiding focuses its rationalization efforts on one specific moment of an organization’s lifecycle being the process of decision-making. The second dimension is the *technical substrate*, i.e. all the concepts and formalisms used to model reality. Mathematics, logic, algorithmics or sociology and psychology are the usual technics used by management tools to build abstractions of reality. Indeed, the selection of one technic over another is not a neutral choice, as it constraints the modelling of reality to aspects approachable by the technic. Practitioners may reach out for more sophisticated formalizations by using a combination of technics through multimethodological approaches (Mingers, 1997), but the limitations remain structurally unchanged. Finally, the third dimension is *organizational simplification*. Actually, all rationalization efforts require the targeting of a subset of stakeholders in an organization. These stakeholders are basically those in charge of using the tool, and potentially those affected by the new knowledge it may generate. For instance, decision aiding is only interested in ensuring that its final recommendations fit the decision maker’s preferences. In so doing, the whole intervention process is centered around the central figure of the decision maker and its first circle of interactions. All other aspects of the organization’s lifecycle remain beyond the intervention’s scope. Very similarly, interventions using knowledge management approaches focus on a subset of stakeholders of knowledge holders and how they acquire and share this knowledge.

These three dimensions describe the intrinsic mechanisms through which management tools’ conception and deployment remain local in their rationalization effort, regardless of the technic used or the aspects of the organization targeted.

- Second, it is fair to acknowledge that management is subject to fads and trends (Birnbbaum, 2000), the promises of which are often followed by disappointments (Dreilinger, 1994) (Carson, Lanier, Carson, & Birkenmeier, 1999). A remarkable consequence for organizations is the accumula-

tion over time of strategic reorientations and structural reorganizations, the distinct rationalities of which have often been translated into new management tools and philosophies. This constant quest for novel approaches leaves organizations with layers of management tools that have been designed at different times to serve different philosophies. Combined with their local character as discussed above, the set of management tools residing in an organization is far less the result of a unique and visionary higher architect and more the consequence of the accumulation of successive rationalization efforts that have not always been anticipated or coordinated.

SOLUTIONS AND RECOMMENDATIONS

By shedding light on the complexity of mechanisms resulting from management tools deployment, this chapter provides additional empirical evidence regarding the need for a deep cultural shift that moves the status of these tools from objective and representative of reality to subjective, partial and context-related. It also reminds managers that the outputs collected through these tools need to be questioned and put into perspective in order to understand their limits and potential to provide strong grounds for building representations of reality or decision-making.

However, one should not throw the baby out with the bathwater. Chains of reaction possibly triggered by management tools, as well as the limited and incomplete character of their outputs, remain valuable means to explore organizational complexity and engage in collective learning. But this comes at a price. First, high level managers should exemplify such a culture by avoiding reflex-based decisions and favor inclusive interpretation processes before reaching conclusions. Second, such leadership needs to embrace a systematic approach that tackles complexity issues throughout the management tools life-cycle. In the following are discussed a set of recommendations organized according to three key life-cycle moments - *diagnosis*, *design* and *implementation*:

• *Diagnosis*

When facing the need to design a new tool or select one from the market, it is suggested the questioning two aspects.

First: what do we really need?

Management tools are usually conceived as means to resolve problems. However, problem formulation is a complex task that deserves full attention. Dewey (1929) noted that problems are nothing but a (necessarily subjective) *sensation of discomfort*. Subsequent decision theory revealed through a descriptive lens how the emergence of problem formulations may follow a chaotic process, in which transient alliances and opportunities for exploiting existing solutions contribute to shaping the problem-formulation process. Through its prescriptive lens, problem formulation is identified as a key part of the decision-aiding process (Tsoukias, 2007), the construction of which should avoid the risk of providing the right answer to the wrong problem.

Second: what do we already have?

The opportunity presented by a new or modified management tool should be examined with respect to the organizational context in terms of the existing ecosystem of tools, as well as the formal and informal practices gravitating around such tools. If possible, upgrading existing and already accepted tools should be given priority. Otherwise, the contextual description should provide a clear representation of the context in which the new tool should fit. Two aspects should be more thoroughly explored:

§ The potential interfaces with existing tools.

§ The risk of existing tools and practices clashing with new developments, and consequently acting as perverse incentives.

• Design

Designing/selecting a new management tool or upgrading an existing one should satisfy two key constraints: inclusiveness and deconstruction.

Inclusiveness implies the early involvement of stakeholders, the activities of which may impact or be impacted by the tool. Their contribution is expected to provide early insights on the possible chains of reactions that the design hypotheses may have on the organization once the tool is implemented. Of course, the quality of the participatory process (Mazri, Daniell, & Tsoukias, 2019) will strongly influence the predictive ability of the group.

Deconstruction is the act of making explicit to future users all the key philosophical, technical and practical hypotheses that shaped the tool's design. In order to perform this deconstruction, one needs to rely on a descriptive model of management tools, like the one by Hatchuel and Weil (1992) that identified management philosophy, technical substrate and organizational simplification as key descriptive features that can be used to highlight the key design orientations. Another model has been suggested by Gilbert (1998) that distinguishes four levels that may serve to design the tool and also deconstruct it - making its key hypotheses explicit. (Fig.2).

Figure 2. Design and deconstruction of a management tool (Gilbert, 1998)

• Implementation

Management tools are hybrids of the artefacts and practice schemes associated thereto (Lorino, 2002). Accordingly, their analysis cannot be performed without taking into consideration the set of context dependent interactions they may initiate.

Given this, implementation is not the phase where the tool is finally cut free and may navigate independently in the organization; rather it's an opportunity to track the sequence of changes it may trigger. Either positive or negative, these changes need to be identified, analyzed and used as sources of collective learning. To do so, terms of interpretation and associated organizational settings (who should participate in this interpretation, when, how interpretations are communicated and to whom) need to be clearly defined and tested to ensure that the tool's outputs are given the required attention.

FUTURE RESEARCH DIRECTIONS

By analyzing management tools through complexity creation, this chapter's ambition was to provide an additional resource to the scientific effort of gaining a better understanding into why management philosophies and models may lead to failure and disappointments. Accordingly, an exhaustive description of the complexity mechanisms associated with these tools did not need to be sought. Those tools discussed above should act as illustrations of the mechanisms that go beyond the technical substrate of management approaches to question the entangled social interactions resulting from their use.

In doing so, two future research directions emerge. First, a more exhaustive description of complexity mechanisms is needed if we want to achieve a better understanding of success and failures in management practices. This requires engaging in ex-post analyses that trace all alterations in knowledge-relations schemes that follow the introduction of a management tool.

Second, these analyses should not be focused on technical aspects alone. Sections above have discussed the extent to which social interactions around management tools, in their formal and informal mode, could be crucial in shaping such tools' effectiveness. Accordingly, it appears essential to systematize the sociotechnical analyses of management tools' success and failure, which should question the very structure of the tool thanks to the decomposition models discussed earlier as well as the social interactions and their impacts on stakeholders' representations. Needless to say, such work takes time, in fact at least the time required for the complexity mechanisms triggered to become visible so to be analyzed with the necessary hindsight.

CONCLUSIONS

This chapter discusses two key mechanisms of complexity creation that illustrate the paradigmatic evolutions of management tools' status from objective and satisfactory representations of reality to partial, subjective and sources of organizational complexity. The fact that these mechanisms strongly relate to formal management models and concepts provides elements of proof in favor of their repeatability in other contexts. They become therefore not only elements of empirical evidence, but also repeatable mechanisms that should capture managers attention.

Indeed, detecting and dealing with the forms of complexities that result from management tools should be at the top of managers' agenda. Two perspectives should be combined at this level. First, deploy the

required monitoring capabilities to observe and track the alterations in knowledge-relations schemes in order to correct them and eliminate negative externalities. The previous section provides elements of investigation that span from diagnosis, design to implementation. Second, use these alterations to develop collective learning about an organizational, and the very often informal mechanisms that shape everyday life in organizations.

Finally, we believe that this kind of research should act as a warning to managers eager to constantly challenge their organizations by adopting very short cycles of change and implementation of new tools, approaches and philosophies in accordance with the latest management trends. It appears that following recent trends comes at a cost, and therefore necessitates the careful calculation of potential costs and benefits before the adoption of such tools.

KEY TERMS AND DEFINITIONS

Artefacts: A human artificial construct bearing a significant meaning in an individual or collective process.

Industrial Safety: The set of methods and models aiming at identifying and managing adversarial consequences of industrial activities on all aspects of environment.

Key Performance Indicators: Synthetic measures of performance against key objectives.

Management Tools: Every mean through which a management technique is conveyed in the organization with the mean of rationalizing at least one aspect of its functioning.

Organizational Complexity: The result of highly connected, interacting, and coevolving entities within an organization.

Rationalization: The process of matching an individual or collective behavior with a set of predefined, not necessarily shared, set of preferences.

ENDNOTES

- ¹ The human relation school of management can also be considered part of behavioral theory. It is however distinguished for the sake of clarity, and further acknowledgment of these two trends diversity.
- ² To be found in technology, human behavior, or management.
- ³ Safety Performance Indicators.
- ⁴ Key Performance Indicators.
- ⁵ Term used in the organization to designate a risk that remains longer than expected in the non-profitable area.

Strategic Thinking

12

César Camisón*University of Valencia, Spain*

INTRODUCTION

Over the last 40 years, strategic management has attempted to provide a normative framework that can be of use to managers in their strategic decision-making. This normative model has featured the typical traits of rational decision-making. The combined efforts of academics, consultancy firms and productive companies have produced a fully-fledged theory of strategy. Furthermore, the contributions of distinguished researchers in the field have given rise to a wide-ranging literature that has helped to guide the training of managers and business leaders, in accordance with the principles and models inspired by the predominant paradigm of the day. The presumed value added by strategic planning even led many large companies to establish specialized departments and allocate significant resources for external consultancies to develop and implement strategic plans.

Despite this, the business world remains plagued by corporate failures, erroneous (or at least misguided) strategies, and inconsistent strategic decision-making (Liedtka, 2000; Chussil, 2005). This raises the obvious question of why, despite the growing knowledge base and information accessible to managers and business leaders, the strategic process continues to be so ill-fated. When called on to speculate about the causes underlying this state of affairs, some have ventured that the reasons may lie in errors of analysis, being lured from the right path by excessive ambition or greed, or other corporate vices. However, the academic debate has leaned towards questioning the normative-rational model of strategic decision-making.

Criticizing traditional approaches to strategic planning has also become the favourite pastime of many business leaders and gurus. The long litany of negative critiques of rational and deliberate planning processes includes arguments that are hard to dispute: that they have lulled managers into a certain complacency by giving them the comforting illusion of certainty; that they have stifled initiative by opting for incremental change over more radical change; that they have emphasized analytics and extrapolation over creativity and proactivity; and that they have denied those closest to the customer a voice in the process. This criticism of strategic planning has emphasized the risks that such transgressions entail in the typical situations surrounding strategic problems, which are characterized by the VUCA environment model (volatility, uncertainty, complexity and ambiguity).

However, when we toss several decades' worth of the strategy literature onto the rubbish heap, what can we replace it with? According to a growing current of thought, the answer is strategic thinking (Dushkov, 2018). This concept has gained an impressive foothold among strategy experts, quickly earning the devotion of critics of strategic planning, who believe in the potential of strategic thinking as a groundbreaking approach to setting strategy that can play a decisive role in maintaining or boosting competitiveness in VUCA environments (Bonn & Christodoulou, 1996). They argue that strategic thinking is the soundest basis for making strategic decisions; indeed, when managers lack this perspective their decisions and subsequent actions are adopted in a way that is fragmented and inconsistent with the company's objectives, that fails to adapt to changes and is lacking in innovation and creativity, thus

DOI: 10.4018/978-1-7998-3473-1.ch128

jeopardizing company performance. This shift in the strategy literature has occurred in parallel with the growing conviction since the 1990s, among the management profession, that top-level managers' main problem is the weakness of their strategic thinking, regardless of whether or not their organizations have formal approaches to strategic planning (Bonn, 2001). The thesis is now the real heart of strategy is the "strategist", a strategic thinker who can discover novel strategies which open views to change the rules of competition and modify the chain of events that define the future (McKeown, 2015).

Although an acceptance of the need for strategic thinking has quickly taken hold among management, managerial competence in this regard has remained at unsatisfactory levels for the past two decades (Garratt, ed., 1995). The concept of strategic thinking, what it really entails, and what it looks like in practice, all remain controversial topics (Horwath, 2008). Indeed, there is currently no consensus as well-developed as that on strategic planning. The term strategic thinking is often used so widely and so imprecisely that it runs the risk of becoming a meaningless notion and one that, like many others, has a minimal impact on managers (Horwath, 2002, Oestreicher, 2017). The empirical research on the relationship between strategic thinking and performance has not reported conclusive results to date (Rajagopalan & Spreitzer, 1997; Vance et al., 2007).

This study attempts to address this concern and how to overcome it. The aim is to present the foundations of strategic thinking. Since learning to think strategically can be understood as equivalent to learning to make strategic decisions, the first step is to define what strategic decisions are and what are the drivers that shape them. Different paradigms have been applied to the analysis of the complex nature of strategic decisions and the factors that influence them (Moon, 2013). Our review of these explanatory frameworks for the strategic decision-making process starts with the rational-analytical model of strategy, based on strategic planning, before then reviewing and criticizing it from the perspective of the adaptive strategic approach. Third, we attempt to provide a well-founded explanation of what strategic thinking is and what skills are required of people who want to develop powerful strategic thinking.

BACKGROUND

Not all managerial decisions are equally pivotal. The repercussions on a company's efficiency and competitiveness vary substantially depending on whether the decisions relate to tackling problems, identifying and exploiting opportunities, managing resources, setting objectives or drafting competition and growth plans in known or new businesses; or whether the focus is on everyday choices about how to carry out repetitive and optimizable tasks and processes that form part of the day-to-day life of organizations. The former are examples of strategic decisions, while the latter should be classified as tactical or operational decisions.

The essential strategic decisions can be summarized in the six questions listed in Figure 1. Therefore, the strategic process starts by defining the strategic objectives and, within those, the area of activity or set of activities where the company wants to compete, which requires a strategic analysis of the attractiveness of different industries. Having made this choice, senior management should then decide how to compete in each of the activities, which calls for competitive strategies for each business. They must also identify the desired growth path in the different markets, choosing between organic growth, external expansion or growth in cooperation with other organizations; the corporate strategy is derived from these choices. The decisions regarding the competitive strategy and the corporate strategy both have at their core the generation and maintenance of competitive advantages. However, in open economies, the forces of creative destruction unleashed by Schumpeterian innovation can thwart any competitor who

does not pay enough attention to the sustainability of their competitive advantages. Therefore, managers must also be concerned about competitive dynamics and the assets at their disposal to constantly renew the company's leading position through continuous innovation—both incremental and radical. No less critical are the decisions aimed at fostering an industry-wide transformation that sets new rules of the game in the market. Since these new rules better suit the company's resources and capabilities, the company—led by the decision-maker—can more easily claim an advantage. The sixth decision-making dimension for senior management focuses on the development and management of the resources and capabilities it needs to compete and grow. For this task, it is essential to manage innovative practices and teams and promote learning pathways.

Figure 1. Fundamental strategic decisions

Strategy can thus be seen as a model that inspires, compiles, systematizes and aligns this set of strategic decisions. To carry out this role, the strategy must act as the axis that balances a series of forces that can exert conflicting pressures on managerial decisions: the environmental challenges come in the form of problems or opportunities; the internal forces of the company that dictate its strengths and opportunities; the means that management has at its disposal to achieve corporate objectives, both in the

form of resources and capabilities as well as beliefs and values; and the orientation and pattern that inspire decisions and courses of action, whether analytical (analysis and plans) or forward-looking and creative.

Although this concept of strategy can cover the opposing dimensions and antagonistic forces that operate in any strategic process, we are still a long way off a generally-accepted description of how managers think and make decisions. Following Johnson & Scholes (1999), we can identify at least six approaches to decision-making, each with different assumptions regarding the factors that guide the choice between the available alternatives:

1. The rational manager approach. This approach reflects the classic concept of the decision-making process, which assumes a context of perfect competition with complete, free, openly-available information. The decision-maker's rational behaviour in an environment of this kind would be aimed at the search for the optimum, for a decision that is better than the other alternatives.
2. The satisficing approach. There has been growing acceptance of the decision-maker's bounded rationality in decision-making, as it has been gradually acknowledged that the information available is imperfect. In such circumstances, the decision-maker's behaviour is no longer aimed at seeking an optimal solution—which does not exist or cannot be identified with the means available—but rather a satisfactory alternative given their expectations. Different acceptable solutions to the same problem can thus be identified, depending on what each agent understands by “satisfactory”.
3. Incremental adaptation approach. The satisficing approach still aspires to a decision-making process executed within the classic means-ends framework. However, the increasing complexity and turbulence of the environment and the challenges it raises have multiplied the possible prospective scenarios and the speed at which they are changing, creating an imperfect or multiple future. The decision-maker's rationality would then be limited by unplanned change. Adaptive behaviour would thus be aimed at a decision-making process focused on learning through trial-and-error, and adopting solutions accordingly.
4. Cultural approach. This approach is also based on an incremental explanation of strategy development, although in this case it emphasizes the fact that the manager's decision-making rationality is limited by the cultural frames of reference for the individual, the organization (paradigm), the industry (recipe book), the profession (trade) and territory (regional/national culture), which will dictate the ethical and economic efficiency limits of what solutions can be considered acceptable, as well as the adoption of certain values and routines. Thus, cultural behaviour predicts a decision-making process attuned to accumulated experience, to ways of doing things that are taken for granted (that is, the unquestioned assumptions and routines that are taken as a given) and to the body of decisions accrued over time, as well as the manager's degree of opportunism.
5. Visionary approach. Decision-makers' rationality can also be limited by their perception of the problem and the organizational goals. In this case, their behaviour would be explained by their person profile. This includes leadership skills, through which their decisions map out the course to be followed by other members of the organization. Strategy would thus result not from a premeditated plan, but rather from the governance of an autocratic leader who uses their authority to impose the decision, or from a charismatic leader who can employ their positive influences (reputation, trust, personality) to ensure that all members of the organization are on board.
6. Political approach. The political dimension is also a source of bounded rationality. The decision-maker works in the cross-fire of the power games between actors and networks of multiple interests competing for scarce resources to achieve objectives that may potentially be incompatible. In doing so, they may deploy processes of competition and coalitions. In this scenario, managerial

behaviour can be described as a process of alignment, in the sense that the strategy is the result of negotiation, persuasion and the mutual accommodation of objectives among stakeholders (to resolve differences in expectations between different groups, preventing potential conflict). The ultimate aim is to balance the diverse aspirations of the group in order to secure agreement as to the most politically satisfactory decision that can reconcile collective objectives.

Strategic planning has its roots in the classic rational solution to the problem of strategic decision-making. Viewed from this perspective, a strategy is a considered plan aimed at orienting activities towards the desired objectives, and which is determined on the basis of a limited number of competitive actions for the company to choose from. The rational analysis of the position should then lead to a process of defining the objectives and the plans to achieve them.

Strategic planning as a “way of thinking” is largely similar to the general process of problem solving. The **rational decision-making model** is aimed at choosing the best alternative in any situation, by following a predetermined series of stages. The first is the intelligence phase, which consists in becoming aware of the problem (the reasons behind the need for the decision to be adopted); next, defining the problem (which means obtaining information); then analysing it (which involves analysing the information); developing and evaluating different alternatives (that is, organizing the information to filter out the most interesting ideas so that the plans/ specific alternatives start to take shape); and finally, choosing and applying the best alternative (according to the selected decision criteria). The strategic plan must therefore be consistent with the analysis carried out, addressing both the opportunities and threats that the position presents, as well as corresponding to the company’s strengths and weaknesses and those of its competitors, and any other factors that may arise unexpectedly in the course of competition.

Well-considered strategy approaches help to provide a better understanding of how to manage the principles and structures that apply to specific positions and can result in decision-makers developing a valuable skill. Strategic planning offers a series of advantages: it facilitates a more systematic, logical and rational analysis of the decision; it enables the company to be proactive rather than reactive when defining its future; it helps members understand what the desired goals are; it helps to evaluate less strategic decisions; it enables progress-checks on the strategy (strategic control); and it empowers more people to participate in the process.

Nevertheless, there are still some significant limitations to the rational paradigm of strategy, and overlooking them can entail a series of risks for the company. Despite its popularity, in reality the strategic process does not always adhere to the norms of rational paradigms. We must acknowledge that, quite often, the search for information is not rational. An additional problem with the rational approach is that it involves the belief that there is an optimal way of competing dictated by the structure of the industry. The problem with this approach is that it offers up a choice of strategies that simply reflects the limited number of alternatives proposed by the literature on the basis of an analysis of the competitive environment for the activity. This position entails accepting the notion of a single possible future and excludes the possibility of diverse capacities, while overlooking the inherent problems relating to innovation and creativity or the possibility of surprising strategies from unexpected competitors.

Academic frustration with the problems inherent in the rational approach to strategy, relating to information, copycat strategies, determinism and innovation, prompted explanations that value cognitive issues, as well as the political and cultural dynamics that can generate *emergent strategies*. These strategies are constructed without intentionality, or even in spite of it (unconscious development of behaviour patterns). A preference for one of these approaches to strategy over the other has triggered impassioned academic debates, including the one led by Ansoff (1987, 1991, 1994) and Mintzberg (1990,

1991, 1994a, b, c), and between Seth & Zinkhan (1991) and Montgomery, Wernerfelt & Balakrishnan (1989, 1991). While one school of thought defends the formal nature of the strategic decision-making process, which should be directed by clear guidelines and carried out on the basis of a rational analysis of the problem, the other argues that it is impossible to *a priori* define planned strategies that delineate the future of the organization, when in fact they can only really be seen *a posteriori*, when analysing the company's past performance.

Nevertheless, when it comes to making strategic decisions one cannot approach it in too cavalier a fashion, disregarding possibilities that may turn out to be crucial. As Simon & March (1958) also argued, one cannot go from a rational model, which is supposed to be capable of producing an exhaustive examination of all decision alternatives and their consequences, to a garbage can model, where problems and solutions are haphazardly mixed together, throwing out decisions at random. Faced with complex decisions, many managers end up making decisions without having properly evaluated the requirements of the situation and the available resources, thus giving rise to unintended consequences.

FOCUS OF THE ARTICLE

The Presumed Dichotomy or Analogy Between Strategic Planning and Strategic Thinking

Strategic thinking has been put forward as an alternative paradigm capable of overcoming the limitations of strategic planning. However, the term is not without its difficulties. The first is of a conceptual nature. The proliferation of studies that employ this concept has generated a great many definitions of the term strategic thinking; however, they do not converge on a single meaning and differ notably in terms of their specific characteristics.

One group of authors (i.e., Morrissey, 1996) has used this term almost interchangeably with other concepts such as strategic planning or strategic management. For example, Wilson (1994: 14), when describing the evolution of strategic planning processes, observed the following: "This continuing search for improvement has profoundly changed the character of strategic planning so that it is now more appropriate to refer to it as strategic management or strategic thinking"

Another line is taken by those who have opted for broad, seemingly all-inclusive definitions, such as that offered by Nasi (ed., 1991): "Strategic thinking extends both to the formulation and execution of strategies by business leaders and to the strategic performance of the total enterprise. It includes strategic analysis, strategic planning, organization and control, and even strategic leadership. Therefore, strategic thinking basically covers all those attributes which can be labeled "strategic".

These pioneering conceptualizations have left serious gaps in the understanding of what strategic thinking is. Their main limitation is that they fail to specify the characteristics of strategic thinking. None of these uses of the term is consistent with the idea that inspired its advocates, for whom thinking is not the same as planning. Thinking is a mental process applied by an individual for achieving success in some game or problem. Then, as cognitive activity, it gives thought. Planning is also a mental process but with objectives very different (Liedtka, 1998b; Bonn, 2001; Graetz, 2002; Abraham, 2005). Within the defenders of conceptual differentiation, it is also possible to distinguish two approaches.

The first conceptualization conveys the idea of a dichotomy between the analytical and creative aspects of strategy making. Thus, Raimond (1996) divides strategic thinking into two modes: "strategy as intelligent machine" (an information processing approach, driven by or based on data) and "strategy

as creative imagination”. Nasi (ed., 1991) differentiates between the harder analytical approach, with its traditional focus on competition, and the softer approach, which emphasizes values and culture. This literature gives the impression that strategic thinking is incompatible with strategic planning, as we understand it. This polarization does not seem advisable since both aspects are clearly required in any serious strategy-making process.

Another perspective holds that thinking strategically and planning strategically refer to sequential processes, at least in cases where good strategic planning helps strategic thinking (Ohmae, 1982, Porter, 1987). As such, the notion of thinking strategically refers to the conception of ideas, the generation and application of knowledge to create business strategies through which an organization meets its objectives. The planning process serves as a tool to help implement the strategy chosen as a result of strategic thinking. The objective of strategic thinking is to discover novel and imaginative strategies that can rewrite the rules of the competitive game and visualize potential future scenarios that are significantly different from the present. Therefore, its essential features are creativity, synthesis and divergence. Conversely, the objective of strategic planning is to operationalize the strategies developed through strategic thinking, and to support the process of strategic thinking. To that end, it is based on analytical, conventional and convergent processes.

For Mintzberg (1994c: 107-108), the term “strategic thinking” is not merely alternative nomenclature for everything that falls under the umbrella of strategic management; rather, it is a particular way of thinking, with specific characteristics. Mintzberg has devoted a great deal of attention to articulating the differences between strategic thinking and strategic planning. He argues that strategic thinking is a process more related to synthesis (connecting the dots) than analysis (finding the dots), “capturing what the manager learn from all sources (both the soft insights from his or her personal experiences and the experiences of others throughout the organization and the hard data from market research and the like” and then synthesizing that learning into a vision of the direction that the business should pursue”. Therefore, strategic thinking cannot be systematized and should involve intuition and creativity. Whereas strategic thinking is the critical part of strategy formation, strategic planning is an analytical process happens around the strategy formation or strategic thinking, by providing inputs for the strategist and programming the implementation of strategies that have already been already identified. Then the outcome of strategic planning is a plan.

Mintzberg argues that rather than occurring hand-in-hand with strategic thinking, traditional planning processes tend to leave no room for strategic thinking, and as a result, they hinder the successful adaptation of the organization rather than support it. Prahalad and Hamel (1996), two other highly influential strategy theorists, join Mintzberg in denouncing traditional approaches to planning, which they describe as “strategy as form filling.” Although they use the term “crafting strategic architecture” rather than “strategic thinking”, the concept involves the same themes of creativity, exploration and understanding discontinuities.

There is a clear need to implement processes and plans to ensure that managers’ packed daily schedules do not cause them to overlook strategic issues. Therefore, we cannot entirely lose focus of strategic thinking definition on the strategy formulation process; what we need is to know how to transform today’s planning process into a way of strategy-making that integrates rather than undermines strategic thinking (Liedtka, 1998a, b). Thereby, as Graetz (2002) writes, strategic thinking and strategic planning are “distinct, but interrelated and complementary thought processes”. In the model of Graetz, the role of strategic thinking is “to seek innovation and imagine new and very different futures that may lead the company to redefine its core strategies and even its industry”; and the role of strategic planning es “to

realise and to support strategies developed through the strategic thinking process and to integrate these back into the business”.

Stacey (1991) approaches strategy through a different lens, referring to the discoveries yielded by the new science of quantum physics and complexity theory. In so doing, he reaches almost all the same conclusions as the authors mentioned above. However, he is wary of identifying future vision as a key driver of strategy, since he sees the strategy-making process as successful when it is founded on “designing actions on the basis of new learning”, rather than following “pre-programmed rules.” He claims that strategic thinking is not “an intellectual exercise in exploring what is likely to happen (...) strategic thinking is using analogies and qualitative similarities to develop creative new ideas.”

Heracleous (1998) distinguishes between strategic planning and strategic thinking with reference to the analogy between single-loop learning and double-loop learning. While single-loop learning involves thinking about strategies within the preestablished framework of assumptions and putting them into action through a fixed set of programmed movements, double-loop learning is characterized by challenging pre-existing assumptions and by developing innovative solutions and actions. The first type of learning would correspond to strategic planning and the second to strategic thinking, although the author points out that both processes are interrelated in a dialectical dynamic, with both being equally essential for effective strategic management.

The Concept of Strategic Thinking

From these ideas, strategic thinking is understood as the mental or thinking process in which individuals make strategic decisions in organizations, with a view to making a difference in terms of results through imagining both innovative and challenging conventional responses to difficulties, and unique insights focused to create competitive advantages for a firm.

Strategic thinking implies some notes:

1. The critical strategic question is not the conventional “what”, as “why” or “how” (Raymond, 2010).
2. Its basis is the will to positively change an organization’s future. Therefore, it includes the capacity for developing a strategic prospective for exploring all possible futures (Conway, 2016).
3. This ability is becoming increasingly crucial to identify and seize opportunities before competitors do, and to prevent risks that may negatively impact the company’s competitive position, when it is in a scenario characterized by complexity, uncertainty, fast-changing, work under the pressure of competition and incomplete or limited information.
4. Strategic thinking incorporates mission, vision and strategy, which tend to be intuitive elements (based on feelings) rather than analytical (based on information). The company vision is based more on the decision-makers’ feelings and perspectives than the results of any systematic analysis.
5. Reaching an agreement on these elements among the members of the company’s management team is an essential prerequisite for effective strategic planning. Strategic thinking is therefore the result of the coordination of creative minds within a shared perspective that visualizes progress towards the desired objectives.
6. It can be a process developed individually or collaboratively. Group strategic thinking should create more value because it enables a creative dialogue among people within share on complex issues.

FUTURE RESEARCH DIRECTIONS

Future research should primarily focus on more precisely delineating the characteristics that define strategic thinking and on drafting practical models that facilitate its incorporation into managerial practice. The lack of a generally accepted definition for strategic thinking leaves open the question of how strategic thinking is different from other ways or styles of thinking.

But there is also no a standardised list of key competencies of strategic thinkers (Hussey, 2001). Strategic thinking integrates elements of 10 other types of thinking (Figure 2). As indicated by Bonn (2001), the defining elements of strategic thinking can be categorized on two levels: individual and organizational.

Figure 2. Types of thinking incorporated in strategic thinking

The first revealing feature of strategic thinking is its positivity. **Positive thinking** (Miller, 2005) implies the will to shape the future and the eagerness to pursue it, without fear of risks and the unknown, trusting in one's own strength and taking responsibility for one's destiny. A good strategist must, by nature, be an optimist, someone who believes in their ability to shape the future and who conveys an enthusiasm for pursuing this goal. As the French writer Maupassant claimed, the only true fear is fear of the unknown.

This is precisely the challenge that the strategy-maker must overcome: the fact that people are typically averse to any processes of change that involve risks. The positive management of change must be able to successfully deal with these fears and emotions. The empirical study of the effects of expecting good things to happen has been developed from Scheier & Carver (1985). The empirical literature review on the effect of positive psychology interventions in organizations by Meyers, van Woerkom & Bakker (2013) concludes this attitude can be a promising tool for enhancing employee well-being and performance.

Second, strategic thinking is **competitive-cooperative thinking** because it is endowed with a competitive spirit but works within a pattern of cooperation. Competitive thinking (Porter, 1987) is focused on achieving objectives in conditions of competition against opponents, who often have irreconcilable objectives of their own. This forces us to make the best possible decisions, in a spirit of self-improvement, as well as to analyse and understand our adversary's strategies. At the same time, however, the strategy to compete requires the cooperation of different resources to lock down a joint strategy. The collaborative problem solving skills have been identified among the most critical competencies necessary for success in the workforce (Oliverly, Lawless & Molloy, 2017).

The mere fact that we are talking about strategy connects this topic to the future. **Proactive-anticipatory thinking** (Alsaaty, 2007; Bindl & Parker, 2010; Wu & Wang, 2011) emphasizes seizing opportunities or anticipating problems in advance, so that, without neglecting the present, it is possible to plan for the future and then strive to make it a reality. Strategic thinking "is not driven by future intent alone" but it is *thinking in time* being able to combine past, present and future at the same time in the mind of strategic thinker to create better strategies (Liedtka, 1998b). This type of thinking therefore incorporates three aspects:

- a) Proactively anticipating what is to come. Compared to "reactive management," which spends its time "putting out small fires," dynamic managers strive to anticipate future events in order to deploy actions that prevent threats and give them a head-start on seizing opportunities.
- b) Taking the initiative to convert the threats or opportunities identified into action plans. Although strategic thinking entails reflecting on the future, it goes beyond an intellectual exercise and must be driven forward by people who take realistic action, and who have the determination to overcome the difficulties in identifying and exploiting opportunities. Their work is intense as they spend most of their time "doing" and identifying and solving problems.
- c) Adaptability. Dynamic thinking shows a great capacity to adjust quickly to changes in the environment.

Such proactivity has been empirically recognized as a positive behaviour than can lead to the increased performance of individuals and organizations, specially when they are required to respond to changing issues (Griffin, Neal & Parker, 2007; Wu & Parker, 2013).

Strategic thinking not only engenders intense activity to identify and solve problems (development of new products, creation of new markets, innovative organizational designs, etc.), but also displays the ability to find solutions that can be achieved through linear or non-linear pathways. Therefore, it requires combining logical-analytical-systemic thinking with critical-creative-intuitive thinking. Below we examine what these two skill areas consist of.

Logical or logical-linear thinking (Hume, 1739, 1748; Newton, 1728, 2004; Cohen & Smith, eds., 2002) is the traditional way of thinking that can be called "mechanistics" or "Newtonian" and is thus positioned within pre-established systems analogical line paradigms developed by Laplace and Newton. Accordingly, it seeks to solve problems and achieve objectives based on logical predictions (linear interpretation of the cause-effect relationships between facts or data and results) and by applying lessons

learned in similar experiences from the past (Vance et al., 2007). This way of thinking results in incremental approaches to change within an existing organizational mindset in order to develop a deliberate strategy (Mintzberg, 1990). However, there is some empirical evidence humans reason deductively on logic problems and they can reach a good level of formal deductive operations if they are educated in logic disciplines (i.e., Bringsjord, Noel & Bringsjord, 1998; Coetzee & Monti, 2018). Together, from Simon (1956), it is widely accepted even in theory it might be possible to make a rational (and therefore perfect) decision, real-world decisions are made using fast and frugal heuristics that would satisfice rather than maximize utility over the long run (Rachlin, 2003).

Logical thinking rests on **analytical thinking** (Turney, 2009; Brown, Moore & Turney, 2012) or vertical thinking (De Bono, 1970), which in turn is based on the linear application of a series of steps following a pre-established and inflexible order and adhering to certain norms that are considered infallible. It works by breaking down complex processes and realities into parts so that we understand their principles and components, which are identified and categorized. We visualize the interrelationships between these components and organize all the information according to pre-established criteria for the achievement of an objective or the resolution of a problem. Therefore, it is deductive, rational and convergent.

Developing the ability to devise plans begins with an objective and exhaustive evaluation of the problem. Strategic thinking raises managers' awareness of the need for an in-depth examination of the market position, going beyond the superficial features of complex situations to understand their structure, and the strengths and weaknesses of both the company itself and its competition. The analysis should be set within the renowned SWOT framework, as well as the processes that lead to such structures.

Under the rational model of decision making, the process of selecting a strategy, a plan or even a movement entails the strategy-maker following a process inspired by the standard problem-solving approach. This is based on a systematic analysis of the problem, which involves collecting, selecting, organizing and applying information. With this approach to problem solving, each idea and action must have an underlying intention and must be supported by an evaluation process as to why one alternative has been chosen over another. This procedure trains its practitioners to make rational decisions, and to be able to give a logical explanation of the reasons for their choices.

But strategic thinking also requires synthesis. As such, it calls for **systemic thinking** (Hamel, 1996; Raymond, 2010; Chussil, 2005), which seeks a global vision of the system rather than just the agent, an understanding of the organization and its environment. Compared with analytical thinking, which typically involves breaking things down into parts, systemic thinking constructs an overarching mental model of the complete end-to-end system of value creation (Liedtka, 1998b). Making up the whole from the sum of its parts uncovers the interconnections between the pieces and gives rise to archetypal structures or patterns. The mind of the strategy-maker is generalist par excellence. "The strategist must have a great capacity for both analysis and synthesis; analysis is necessary to assemble the data on which he makes his diagnosis; synthesis in order to produce from these data the diagnosis itself" (Beaufre, 1965).

It is undeniable that rational analysis supported by logical-analytic-systemic thinking can provide many useful ideas. But logic, analysis and synthesis are only three of the components of strategic thinking, which also involves critical vision, open-mindedness, intuition, creativity and innovation. They all follow non-linear paths of thinking, which diverge from the known linear pathways. Moreover, strategic thinkers are often characterized by their ability to find innovative and creative solutions, which they generally prefer to solutions which have already been tested and proven. As Liedtka (1998b) indicates, strategic thinking is *hypothesis driven* and so ensures that both creative and critical thinking are incorporated into strategy making. The empirical research of critical factors for strategic success born from creative and analytical thinking points out it is non-linear thought that is the main responsible for an improved score

(Hussey, 2001). But there is also empirical evidence managerial thinking is a continuum identified with the linear and non-linear patterns of thinking which are used in different contexts: linear thinking pattern should be used in structured and static situations or problems, while non-linear thinking patterns produced better decisions when out-of-the-box decision-making are required (Bratianu & Vasilache, 2010).

Open-minded and critical thinking (Lai, 2011; Chatfield, 2017; Lovell, 2018) involves breaking free from the pre-established systems, conventions, and truth systems. Critical thinking is the ability to think rationally, and to evaluate the information presented to us, as well as our own thoughts. The idea behind this concept is to give us a greater capacity to identify true and false ideas and ideologies. Along with knowledge and technique, creative thinking is essential in order to break down the barriers of routine when defining objectives and plans. With creativity and imagination, options can be found that a routine analysis would fail to unearth. While logical thinking assumes positions within pre-established systems and paradigms in line with similar past experiences, strategic thinking also implies the ability to break free from pre-established systems, conventions, and truth systems. **The strategic thinking process does not look for out-of-the-box thinkers, but rather critical thinkers**, who question the information they receive and make sound decisions on the basis of clearly established objectives.

The reason why this mental process needs to be developed is because these days we are faced with thousands of readily-available sources of information, which, unfortunately, are not always genuinely grounded in a rational way of thinking, based on real knowledge that has been challenged. Critical thinking is the tool that allows us to evaluate the new pathways that an open mind will put in front of us. It is the mental process that we must follow to objectively choose the most appropriate way to reach the goal that we have set.

Creative thinking thus challenges the conventional mental model with: (1) an open-mindedness that allows us to weigh up facts that were not initially considered and so find pathways that are normally overlooked; (2) a forward-looking orientation that allows us to anticipate the actions that will be triggered by our strategy and to anticipate measures to address them (De Bono, 1970; Katz, 1997; Hussey, 2001; Runco, 2004; Sternberg, 2006).

Intuitive thinking (Sadler-Smith & Shefy, 2004; Dane & Pratt, 2009) is the unconscious process of making quick—though not necessarily irrational—choices, based on distilled experience and instinctive reasoning. Experts accumulate experiences and classify them, consciously and unconsciously, in the form of cues or patterns that they can later use to choose one option or another without the need for exhaustive analysis.

Lastly, **dynamic-adaptive thinking** displays an aptitude for rapidly adjusting to changes in the environment. The ability to adapt is thus one of the most relevant skills in a company. It is the key to determining whether the strategy that was successful in the past may now be leading us to failure. Managers therefore need skills to align their organizations with their environment (Senge, 1990). Liedtka (1998b) talks about *intelligent opportunism* in the sense of responsive attitude in front of good opportunities: “The dilemma involved in using a well-articulated strategy to channel organizational efforts effectively, and efficiently must always be balanced against the risks of losing sight of alternative strategies better suited to a changing environment”.

The empirical research has confirmed strategic thinking can help business leaders both to develop confident forecasts and to reduce the uncertainty of strategic decisions (Barnett & Berland, 1999), but the relationship between strategic thinking and performance shows uncertain findings (Rajagopalan & Spreitzer, 1997; Vance et al., 2007). Whereas authors as Hambrick & Schechter (1983), Haveman (1992) and Zajac & Kraatz (1993) reports a positive relationship, other researchers have found strategic thinking is associated with a low performance (Jauch, Osborne & Glueck, 1980; Singh, House & Tucker, 1986),

there are mixed results (Smith & Grimm, 1987) or not are significant relationships (Zajac & Shortell, 1989; Kelly & Amburgey, 1991). This state of the question indicates strategic thinking has a hard challenge to improve firm competitiveness and performance, because requires reconciling competing hypothesis about the industry and firm futures and integrating divergent views into a coherent strategy. The contradictory findings in empirical research show the effects of strategic thinking on results are not direct, as explicitly or tacitly a lot of prior studies have assumed, but they depend on the conjunction of a varied portfolio of capacities integrated by different thinking modes. However, we know little about how developing these key skills for strategic thinking (Casey & Goldman, 2010). Therefore, it is necessary to promote longitudinal research that allow us to better understand the process of training of the ability to think strategically.

CONCLUSION

Starting from the premise that equates learning to make decisions with learning to think, this article conceptualizes intelligent decision-making as clarity of thought (not clairvoyance) based on uncertain and incomplete information. A good decision (and a good strategy) will probably be a shrewdly calibrated combination of rational analysis and pre-emptive actions based on the economic logic stemming from the dominant paradigm in the management team, along with a good dose of intuition, judgment, experience and an ability to unlearn the established models and explore new ones.

“Change for the sake change” should be avoided, but we should bear in mind that inability to change can be disastrous. The strategic plan must be well defined such that it involves the least change possible. Frequently switching plans is often an obstacle to achieving excellent results. Thus, once a strategy has been chosen, the company should execute it consistently. But great managers are always willing to modify their plans according to the circumstances. The competitor is a key element in the game, as it has the power to alter the course of the situation; to win, the strategy-maker must adapt to this shift by changing the plan and outmanoeuvring competitors to build a sustainable competitive advantage. The emergent approach is necessary to maintain this adaptive climate. Great managers excel at detecting these emerging opportunities and are thus always willing to modify their plans to take advantage of them.

Shifting circumstances and management’s constant efforts to improve strategy mean that a company’s strategy evolves over time. Strategy is always temporary and is being tested or is evolving. Thus, strategy-making is a process and not a one-off event. Strategic thinking should therefore view strategy not as a single, long-term detailed plan that must be followed to the letter, but as a portfolio of future options. Strategic thinkers work with a considerable range of strategic plans, with a series of consecutive plans. Given the prevailing uncertainty in any position, the strategy only aims to define a long-term vision of where the company wants to go and how to get there, but always allows a degree of flexibility to adapt to the circumstances.

KEY TERMS AND DEFINITIONS

Creative Thinking: This is the type of thinking that challenges the conventional mental model with an open-mindedness that allows us to weigh up facts that were not initially considered, and thus find pathways that are normally overlooked. It encompasses a forward-looking orientation that allows us to anticipate the actions that will be triggered by our strategy and to anticipate measures to address them.

Critical Thinking: This is the type of thinking that involves breaking free from the pre-established systems, conventions, and truth systems, and that questions the information received to detect false or obsolete paradigms. Along with knowledge and technique, creative thinking is essential in order to break down the barriers of routine when defining objectives and plans.

Emergent Strategy: The type of strategy that is formed without an intentional, deliberate plan, or outside of such a plan. Its basis is the unconscious development of patterns of behaviour inspired by cultural and cognitive standards.

Strategic Decisions: These are the management decisions considered pivotal due to their impact on the company's efficiency and competitiveness. They concern how to tackle problems, identify, and exploit opportunities, manage resources, set objectives or draw up competition and growth plans in known or new businesses.

Strategic Planning: This is the process aimed at developing a deliberate plan that orients the company's activities towards the desired objectives. It is based on the systematic and analytical analysis of the competitive position and the model of the rational decision-maker.

Strategic Thinking: Strategic thinking is a particular way of thinking about new strategies, whose characteristics include a taste for competition, an optimistic outlook, the combined application of data and logic, judgment based on experience as well as critical assessment, intuition, creativity and imagination, and a global vision—all aimed at creating a completely new perspective.

Strategy: The strategy is the path that is consciously and purposefully chosen (from a number of alternatives) by the management of the company to mobilize all its resources and capabilities over the long term in order to compete in selected markets and adjust to the challenges of the environment. The company can thus provide value to consumers, achieve a sustainable competitive advantage that can be defended against competition, meet its strategic objectives and satisfy all its key interest groups.

Neurostrategy

César Camisón

University of Valencia, Spain

INTRODUCTION

One of the most prominent and fascinating advances that have helped us to understand many of the facets of human behaviour in organizations is the rise of the interdisciplinary approach. This is especially true when it comes to the role played by management experts in formulating and implementing their organization's strategy, and in the subsequent results. Of all the disciplines that currently have implications for strategy, particularly notable is the interdisciplinary contribution from the field of neuroscience (Butler, 2014). Following the path opened up by the Human Genome Project, neuroscience took an exponential leap forward when the United States government declared the 1990s to be the Decade of the Brain. The rapid expansion in research continued during the first decade of the 21st century, known as the Decade of the Mind. The advances made in our understanding of the complex network of interconnections between the language of the brain and of the mind has radically expanded the frontiers of neuroscientific knowledge.

More advanced knowledge about the human brain has brought with it a deeper understanding of its internal functioning. At the same time, this has called into question the key premise of economics, which views people as utilitarian individuals who make completely rational economic decisions. Since economics has thus far been the most influential discipline behind strategy theory, managers should attempt to understand the principles of behavioural neuroscience (Glimcher & Rustichini, 2004; Lieberman, 2006). This field highlights the capabilities of the human brain; however, it also raises awareness of its inherent risks, habits and oversimplifications and their implications in terms of decision-making, given that they are behind a lot of bad economic and business decisions.

Although the study of the biological bases of human behaviour in organizations is still in its infancy (Zyphur et al., 2009: 70) and the application of this knowledge to managerial practice does not seem to be on the immediate horizon (Balthazard et al., 2012; Peterson et al., 2008; Waldman et al., 2011), there is a broad current of thought endorsing the benefits of neuroscientific decision-making research and the role played by emotions, gestures and symbols, semantic processing, human interactions and neuronal connections, almost to the point of putting knowledge of the human brain at the very core of modern management. In 2004, the magazine *Frontiers in Human Neuroscience* published a special issue on *Society, organizations and the brain*. In the field of management, it is worth mentioning the study on "Information, attention and decision making" published by the Academy of Management Journal in June 2015.

Hannah et al. (2013) describe a cognitive revolution driven by an understanding of the mental processes that explain people's behaviour and effectiveness. They argue that this paves the way for a multidisciplinary and multi-method approach to the conceptualization of organizations and their management. Neuroscientific research applied to human behaviour in organizations could thus be seen as providing profoundly innovative, heterodox and even radical ideas, and it may also give rise to new approaches and methods aimed at uncovering the human decision-making process, in a way that would otherwise be

DOI: 10.4018/978-1-7998-3473-1.ch129

unattainable. This could represent a significant step forward in knowledge about how to more effectively design and govern social groups with predetermined objectives.

Neuroscience promises especially significant contributions to strategic management research and practice. This discipline is focused on studying the behaviour of a specific type of decision-makers and decisions: those of a strategic nature. There is an ongoing debate about the pros and cons of substantive collaboration between neuroscience and strategy, in a field referred to as **neurostrategy** (Powell, 2011; Ascher et al., 2018). An emerging literature has argued in favour of the potential of neuroscience to improve our understanding of the biology of the brain and how it links to economic and financial decisions (e.g., Camerer, Loewenstein & Prelec, 2005; Camerer, 2008). An emergent notion is that strategic management needs neuroscience and can benefit from its research in three ways: by validating constructs, testing theory, and informing strategic practice. But the intellectual boldness entailed in ideas about the neuroscience of behaviour, and the direct threat that these ideas pose to established, accepted paradigms have shaken certain disciplines, which claim such notions are incompatible with the conventional heuristic approaches of their fields of study. Therefore, there is a notable school of thought that has criticized the application of neuroscientific research to economic decision-making and to management and organization studies (Gul & Pesendorfer, 2008; Bernheim, 2009). Regarding the criticism of the application of neuroscientific research to organization studies, and by extension to strategic management, it poses some relevant theoretical and methodological challenges, rightly identified by Lee, Senior & Butler (2012). This line of criticism advocates a careful evaluation of the organizational applications of this field (Foxall, 2014), while some even directly rule out the notion that neuroscience can make a positive contribution to the advancement of management (Lindebaum, 2013; McLagan, 2013).

As Butler et al. (2016) point out, behavioural neuroscience “is at a crossroads in its theoretical development”. Healey & Hodgkinson (2014: 76) succinctly capture the state of affairs in the following terms: “At one extreme, advocates such as Becker et al. (2011) are calling for a new, biologically rooted, subfield that aims to map neural mechanisms as the prime causes of organizational behaviour (...) At the other extreme, scholars are warning that applying neuroscience to management and organization studies is a dangerous distraction”

This article presents a review of the literature that analyses the contributions of behavioural neuroscience to the study of managerial decision-making and offers a critical evaluation of its implications for management and organization studies, especially in the field of strategy. First, the paper explains the scope of Neuroscience as discipline and its developments applied to social sciences, with the purpose readers can understand its potential to explain human behaviour in general and the economic behaviour specially. Second, it reviews the most recent literature on neurostrategy by developing its implications to understand the mind of the strategy-maker and so approximating to the authentic expert judgement in strategy. The analysis continues by offering both an approximation to the possible applications of the neuroscientific knowledge to managerial practice with the objective to identify and prevent some problems as cognitive biases, and useful recommendations for decision-makers. The description of the forms of strategic behavior categorizes them into four models: rational, limited rationality, psychologically motivated and biologically induced. Finally, the paper maps out the main strands of the debate in the future.

BACKGROUND

Neuroscience is a relatively new discipline that seeks to better understand the neurological and cognitive bases of human decisions and actions. It incorporates the contributions of a set of scientific disciplines

that study the structure and function, biochemistry, pharmacology and pathology of the nervous system, as well as how the different elements interact, giving rise to the biological bases of behaviour.

At the highest level, interest is focused on the contributions of the emerging field of **behavioural neuroscience**. This is an eminently interdisciplinary field, bringing together neuroscientists, economists and psychologists (Ochsner & Lieberman, 2001; Glimcher & Rustichini, 2004). Lieberman (2006) defines this subject as dedicated to the study of human brain processes to allow people to better understand themselves and others. The discipline incorporates three areas of work: social neuroscience, concerning the relationships between brain mechanisms and aspects such as trust, cooperation, altruism, reputation or social status; cognitive neuroscience, centred on the biological underpinnings of decision-making; and affective neuroscience, exploring the relationships between brain activity and feelings and emotions. Nowadays, behavioural neuroscience provides a new way of understanding the brain and consciousness that is sure to change current conceptions about the mental processes involved in human behaviour and their biological bases.

The discipline that is being formed through the application of behavioural neuroscience theories and methods to the field of organizational studies has been labelled **organizational cognitive neuroscience** (Butler & Senior, 2007; Senior, Lee & Butler, 2011; Senior & Butler, eds., 2007)¹. Senior, Lee & Butler (2011: 805) define organizational cognitive neuroscience as “a genuinely multidisciplinary approach (...) [that may] incorporate the use of prior knowledge of brain systems to develop new hypotheses about organizationally relevant issues.” Within the framework of organizational cognitive neuroscience, there are a number of works that combine its theories and methods to explore questions of interest in the field of organizational studies. These include attempts to better understand the cognitive bases of decision-making and the actions of business leaders, in order to provide recommendations on exercising a managerial role, and to analyse and understand human behaviour within organizations. This literature is also concerned with gaining a deeper understanding of key aspects of the biology of the human brain, in the hope that it will provide ideas to characterize good leadership, and will offer equally valuable lessons on how to become a better leader.

The term **neuromanagement** was originally proposed by Quingguo Ma (2006), director of the Neuromanagement Laboratory of Zhejiang University, to designate the scientific field that relies on organizational cognitive neuroscience and technology to explore the brain activity and mental processes involved when people face typical management problems, such as decision-making, as well as other key social behaviours in organizations such as leadership or teamwork. As such, its focus of attention is on the micro-mechanisms of managerial activity, which it studies via an interdisciplinary approach that integrates management science, economics and cognitive neuroscience.

Within neuroscience there is a field of special significance for strategy: neurostrategy. Despite the broad domain covered by neuromanagement, a new field of knowledge has emerged; Powell (2011) coined the term neurostrategy to define it, describing it as “research at the intersection of strategic management and behavioural neuroscience”. As such, neurostrategy is the discipline dedicated to uncovering the process of formulating and implementing an organization’s strategy, by examining the biological determinants of the functioning of the strategy-maker’s brain.

Working in parallel, the study of non-rational choice behaviour and its impact on human health and well-being comes under the term **behavioural economics**. The principal differences between this and the dominant economic paradigm is that it takes into account irrationality and environmental influences on the dynamics of choice behaviour. This new perspective of economic decision-making represents an intersection of psychology and microeconomics (Jarmolowicz et al., 2015). A seminal contribution to cognitive psychology was that of Daniel Kahneman, who in 2002 was awarded the Nobel Prize in

Economics “for having integrated insights from psychological research into economic science, especially concerning human judgment and decision-making under uncertainty”. Kahneman’s principal contribution to economics was prospect theory, which he developed together with Amos Tversky (Tversky & Kahneman, 1974, 1981; Kahneman & Tversky, eds., 2000). The central postulate of this theory is that, in conditions of uncertainty, people do not make decisions based on the probability of greater gains but rather are guided by a series of heuristics (Kahneman, Slovic & Tversky, 1982). Following the path of the cognitive approach, behavioural economics research (Thaler, 1980; Russo & Schoemaker, 1990; Baron, 1994; Hammond, Keeney & Raiifa, 1998; Thaler & Sunstein, 2008; Camerer & Loewenstein, 2004; Kahneman, 2011) has focused on the cognitive biases and emotional factors that influence individuals’ decision-making preferences.

Powell (2011: 1495) set out four key questions that could be used to judge whether the neuroscience-inspired programme of empirical research on strategy is positive and promises to be of value:

1. Does it focus on a core problem in strategic management research or practice?
2. Does it pose pressing new questions for neuroscientists?
3. Has it been neglected in other fields and is it likely to remain so?
4. How does the neuronal evidence improve our understanding, by validating constructs, testing theory or informing strategic practice?

FOCUS OF THE ARTICLE

The Study of Core Problems of Strategy From the Rational Paradigm and its Criticism

The first critical theoretical point to be resolved regarding neurostrategy is whether it can contribute to a better understanding of core strategic management issues. It would only make sense for strategy research to ask questions about the brain if it helped us to better understand the mechanisms of strategic decisions. Therefore, a first step should be to identify core strategic problems.

The essential strategic questions are: where to compete, which forces us to analyze the attractiveness of the structure of the different industries, consumer trends, the dynamics of competition and to decide the portfolio of activities of the firm; how to compete, which involves designing competitive strategies in each business; how best to take advantage of the resources and capacities to grow, which forces us to choose between the various growth strategies (alliances, mergers, etc.); how to maintain and increase the competitive advantage, which leads to think about the differentiating elements in which to sustain a unique positioning in the market; what will be the profit model; how strategic movements will be organized in time and place; and how to change the rules of the game, an aspect that refers to decisions aimed at transforming the industry and the market for the benefit of a competitor.

Many of the phenomena studied in strategic management (for example, the analysis of an organization’s strengths and weaknesses, the competitive dynamics in a business or the competitive structure of an activity) occur at supra-individual levels or at levels above the behaviour of the CEOs; they occur, for example, at the level of the company, the industry or the strategic group. This approach to strategy is inspired by neoclassical economics, and is essentially concerned with the competitive game in the markets, not the company or with the individual psychology and behaviour of the managers (Simon, 1991). The *Homo economicus paradigm* thus emerges in its fullest sense within a markedly deterministic explana-

tory model of the economic behaviour of organizations: agents' behaviour and results are determined the impersonal game and the automatic adjustment of supply and demand, that is, **Adam Smith's invisible hand of the (aggregate) market**. The manager is not given any weight, and is limited to choosing the optimal alternative in a context of information that is complete, freely available and free of charge.

The approach of economics applied to the research of the bases of expertise in organizational management gave rise to the **normative rational decision-making paradigm**. This perspective is purely concerned with the means of achieving certain objectives, and therefore massively simplifies the intra-firm decision-making process and the human role therein. This vision conceptualizes strategy as an intentional plan to achieve goals that are consciously set following rational analysis. The classical paradigms in economics and strategy have thus paid scant attention to the role of managers in decision-making. Its axis has revolved around the development of tools for the rational analysis of problems and the efficient choice of alternatives in terms of cost-benefit. The managerial development has therefore concentrated on the mastery of these techniques and their rigorous application.

The **general model of the rational problem-solving process** (Figure 1) assumes that human beings (both managers and non-managers) are rational decision-makers quasi-programmed to produce logical solutions to perfectly identified problems. This approach involves considering the process of perception, analysis and decision-making as occurring in a black box.

Figure 1. The strategic decision-making process according to the general black box model of problem solving, based on the rational theory of perception

However, the idea that entrepreneurs, managers and leaders in other organizations—whether for-profit or not-for-profit—are first and foremost conscious rational beings, with absolute power to control and make their own choices and select the optimal option, is increasingly being called into question. The limitations of the rational paradigm have prompted another stream of research on how the decision-making process unfolds. The common thread running through it is the need to model non-rational economic behaviour.

The first attempts to draw attention to the need to formulate new theories of strategic choice came in the 1950s. The main line of criticism came from the seminal works of March & Simon (1958) and Cyert & March (1963) on the role of agents (with their own interests and objectives) in organizational behaviour and the **bounded rationality paradigm**. This approach sets agents' decisions within the context

of the imperfect information available, and the expectations they have which dictate what results they consider satisfactory.

Within the strategy literature, some pioneering lines of research have explored certain *psychological foundations for strategy-makers' behaviour and decision-making* (Hodgkinson, 2008). The initial phase has resulted in interesting insights into decision-making preferences and the way in which strategies are developed. The first such contribution came from the upper echelon theory, which focused on the influence of the top management teams' individual and sociodemographic characteristics (such as gender, age or training) as well as environmental stressors (Hambrick & Mason, 1984). Hambrick & Fredrickson (2001) emphasize that the key to a successful strategy is to achieve a solid consistency between the elements of the strategy that have non-linear relationships among all of them. Since the development of the strategy is not a linear and simple process, the great strategists are interactive subjects and of cyclical and systemic thinking (Quinn, 1980). A parallel agenda has influenced the study of managerial attention (Cho & Hambrick, 2006), managers' perception and use of information (Powell et al., 2006) and deliberate learning processes (Zollo & Winter, 2002) as drivers of their efforts to seek out and select a strategy. Along with this paradigm, certain schools of thought on strategy subsequently emerged that were critical of the rational vision and espoused the idea of strategic processes characterized by adaptive learning and trial-and-error (Mintzberg & Waters, 1985; Mintzberg, 1991).

The Mind of the Strategy-maker and Expert Judgment in Strategy

Viewing the managers themselves as components of the decision-making problem represents a great step forward in gaining a clearer understanding of the importance of the decision-maker's profile in determining how strategic decisions are taken. Although the general model of the rational problem-solving process was a valuable starting point for the study of the decision-making process and provided a basis for developing the rational paradigm of the strategy-making process, it is generally accepted these days that, in many cases, the search for information and alternatives is not rational. The impersonal explanation of strategic decision-making as a rational process omits the strategic process is biased and limited by the decision-makers' perception and cerebral activity. The limitations of the rational approach become evident in problems relating to information, to perception and to the choice of strategy.

The problem of information. Viewing strategy as a plan implicitly entails the assumption that the decision-maker can control the strategy on the basis of their calculations. Drawing up a plan requires an interactive reading the chains of actions and decisions, whereby the decision-maker has to anticipate the consequences of their own decisions and interactively respond to competitors' decisions. The problem that emerges is the complexity involved in assessing all the consequences of the different decisions and competitors' responses. The cost entailed in finding out about all the alternatives and uncertainty about the future, as indicated by Simon (1947), can prevent or seriously hinder the identification of the optimal decision. The information that a rational decision-maker needs in order to make optimal strategy decisions is not readily available, especially in complex and changing environments. This complicates the analysis, as well as the identification of opponents' possible responses and the alternatives themselves.

The problem of perception. The rational approach to strategy also effectively erases the problem of managerial perception in strategic choice. The limitations of the rational approach to strategic decision-making are not only due to the complexity of the scenario and the lack of information, they also relate to how this approach disregards the biological imperative. The asymmetric perception of results (Kahneman & Tversky, 1979) represents another knock to the idea of the optimal choice. Cognitive psychology has shown that perception and decisions are directed by the brain, and that this is not the coldly rational,

Figure 2. The problems of receiving and interpreting information

deliberate computer that we often imagine. Hence the problem of perception. The way in which the decision-maker receives and interprets external informational stimuli does not follow the logical, rational and objective model described above; as such (Figure 2):

1. In the intelligence phase, awareness or recognition of the problem may take some time or may not occur at all. There may also be a loss of objectivity, because the sensory stimuli received by the decision-maker do not capture his/her attention, are misinterpreted, or are undervalued due to the poor reliability of the sources. The very nature of the problem also conditions the decision-maker's perception of the opportunity. There may thus be problems of reception.
2. An inaccurate picture of the situation may be formed during the formulation phase of the problem. It may even be a long way off the true reality, due to imperfections in the informational stimuli and other brain mechanisms specific to each individual. A second category of problems therefore relate to interpretation. Just as markets are analysed with a series of instruments provided by strategic management to seek out imperfections that can be exploited or against which to defend themselves, the brain also has its imperfections, and strategy-makers must guard against these.

3. The analysis of information and the formulation of strategies can be “contaminated” by aspects internal to the decision-maker, such as their skills in handling different types of information (qualitative, statistical, computational, etc.), their preferences (which may lead to opportunistic decisions) or their psychological circumstances. Relevant discoveries have been made concerning the **cognitive biases** that influence individuals’ decision-making preferences, such as loss aversion, the sunk cost fallacy or reward discounting (Tversky & Kahneman, 1974, 1981; Ainslie, 2016).
4. The appraisal of the results achieved with the chosen alternative may suffer from the same problems of subjectivity, opportunism and uncertainty that affect the decision itself.

The individual elements that determine the decision-maker’s perception of a situation can be categorized into three groups:

- Information factors. Of course, information asymmetries such as the level of access to and the recency of the accumulated information can partially explain these behavioural asymmetries.
- Psychological or attitudinal factors. Among the psychological factors that influence the perception of a problem, the main one is the conception and playing style of those involved. Trade-offs may sometimes be due to different perceptions of the dynamics of the positions.
- Cognitive factors or factors related to the ability to compile, process and apply information, as well as learning and experience.

The problem of creativity in identifying and selecting strategies. The last problem associated with the rational approach is the difficulty in articulating the possible decisions that the company can take based on the information available, and choosing the most suitable option for the situation in question from among all the possibilities. An organization’s search for its own alternatives and attempts to identify those of its competitors is often muddled and lacking in logical criteria.

One way to prevent this problem is to massively simplify the alternatives available to managers from which to define their strategic response, offering different types of theoretically distinct strategies. The second way to simplify the problem of identifying and selecting strategies is based on the hypothesis that there is an optimal way of competing dictated by the structure of the industry. When it comes to drawing up a plan of action, the classic rational paradigm of the strategic process adopts a structuralist perspective. Under this perspective, the company must orient its strategy towards achieving a competitive position in the market that allows it to prosper by effectively taking advantage of the opportunities offered by the structure of the industry or shaping those opportunities to suit its own needs. In addition, the paradigm holds that within the structure of each sector (which is taken as a given, even though it is recognized as an endogenous factor), there is an optimal way to compete and in order to discover it, the company must conduct a thorough situational analysis.

These approaches follow a deterministic reading of the effect of the competitive environment that completely overlooks the role of managerial discretion and perception. The problem with this approach is that it ends up producing copycat strategies, chosen from among the limited number of alternatives suggested by the literature on the basis of an analysis of the competitive environment for the activity. This position entails accepting the notion of a single possible future and, by restricting the problem of strategic choice to the selection of the strategy recommended by the structure of the industry, neglects the possibility of innovation and surprising strategies from unexpected competitors.

Furthermore, criticism of the rational perspective has effectively highlighted a key pitfall: no matter how much theory there is on a particular position and no matter how deterministic the path to be followed

in that position, real-world experience has shown over and over again that decision-makers take very different paths even in contexts where there is a high degree of convergence in terms of recommended approaches. There are three implications to this:

- (1) Although managers are subject to the deterministic reading dictated by the most widely-recommended deliberate strategies, their personal interpretation may differ depending on their ability to “read” the situation in order to take advantage of imperfections, guard against threats to the organization and develop effective actions to exploit opportunities.
- (2) The situation does not mechanically determine the decision-maker’s response, since those involved have free will and their own style and personality. Along these lines, Day & Nedungadi (1994) hold that it is the manager’s process of perception that gives meaning to the data stemming from the situation, and this is what leads to the selected strategy.
- (3) Managers can also differ in their desired vision (for the company and the surrounding environment), thus giving rise to differing perceptions of the resulting performance, which in turn could lead to organizational conflicts or ineffective, misaligned actions.

The vast strategy literature on organizational resources and capacities that has emerged since the 1980s has been pivotal to gaining an understanding the causes of the differences in a company’s strategies and results. However, it continues to rely on aggregate approaches to explain firm-level heterogeneity. Under these paradigms, the only step taken to uncover heterogeneity at the infra-firm level has been to shift the focus from the product market to the factor market, thereby identifying an organization’s group competences and managerial capacities (Camisón, 2005), as well as the processes of creation, absorption and application of knowledge flowing through it (Camisón & Forés, 2010). However, such analyses have been limited to a competitive assessment of these capabilities, without delving into the critical issue of how the interaction between individuals and organizational processes can promote (or prevent) the development of such competencies.

Neuroscientific Approach to Core Problems of Strategy

Research within behavioural economics has helped identify a series of irrational prejudices that appear in economic, financial and strategic decisions. However, the cognitive-psychological explanation leaves many questions unanswered. The most important outstanding issue is why people make non-rational decisions, how such decisions coexist with rational decisions, and how both types of decision are made by successful experts, entrepreneurs and risk managers. The based-psychology research has also produced results with limited normative and predictive capacity and thus has done little to improve managers’ emotional regulation or control over their behaviour.

The reason of this limited utility of non-rational models of strategic process to guide the improvement of the managerial decisions quality is they involve an inherent contradiction: trying to explain how managers think about strategies, while dodging the fact that strategy formulation is a cognitive process that takes place in the mind of the strategy-maker and therefore has a neurological basis. Strategy is the product of strategy-makers’ perspectives and perceptions of their environment and of their understanding of the messages it sends them; however, these perceptions and preferences are conditioned by their brain mechanisms or genetic differences.

Research into the biology of the brain and its association with economic and financial decisions has led to a line of study that examines the relationships between individuals’ neuronal and genetic profiles

on the one hand, and economic behaviour on the other. Interesting results have been reported, especially regarding an explanation for risk preferences (Glimcher et al., eds., 2009; Kuhnen & Knutson, 2005). Evaluation of future rewards has also been correlated with neural bases, pointing to a neural underpinning of risk aversion (Tom et al., 2007) and a neural explanation for why future gains and losses are discounted asymmetrically in the brain (Gehring & Willoughby, 2002; Knutson, 2008; Xu et al., 2009). This diverging assessment of results also appears in the evaluation of information (Minas et al., 2014).

Especially interesting for neurostrategy is everything we are learning about the **executive brain (the E factor)**. In 2001, Elkhonon Goldberg provided a masterful account of the executive brain in his book of that name. In recent years, neuroscience has attentively studied the **executive functions** of the brain, so called because they are the functions that organize all the other functions (intellectual, emotional and motor) and direct them towards a goal. It seems inevitable that the metaphor of the conductor of the orchestra would be employed here, and indeed it was used by Goldberg in chapter 6 of his work.

Figure 3. The neuroscientific model of decision-making based on neuronal dynamics

The new **neuroscientific model of decision-making** (Figure 3) thus defines human beings as partially rational decision-makers with freedom, diversity and a limited capacity to produce logic-conditioned responses to imperfectly identified problems. Under a rational strategic approach, the cerebral mechanism

underlying decision making supposes that the reception of a sensory stimulus (external information) increases neuronal activity and a decision is reached when this activity exceeds a certain threshold. In the presence of a weak stimulus, or in the absence of a stimulus, neuronal activity would stem from background brain activity, that is, neuronal noise. As such, the decision would display a random behaviour, which could explain why the subject claims to have received a stimulus even if it has not been applied. However, a recently published study (Carnevale et al., 2012) provides evidence that contradicts the prevailing theory regarding brain activity when we make decisions based on perception.

The positive contribution of neurostrategy to the understanding of the strategic decisions has not been accepted peacefully by the academy. The principal criticism emphasizes the inability of neuroscience to test economic and strategic models because such models do not make predictions about the brain (Gul & Pesendorfer, 2008). Critics also dispute the idea that a better understanding of the decision-making process leads to better choice models (Bernheim, 2009: 38).

SOLUTIONS AND RECOMMENDATIONS

Despite the expectations created, there has been very little progress made in the study of the mind of strategic management experts. This is largely because, unlike with other activities, it is difficult to measure their level of skill and subject them to experiments in their natural environment. There is therefore a need for research in lab to determine whether the brain mechanisms of strategic management experts follow the same patterns as those already identified in other disciplines.

Research in neurostrategy also needs to advance in the formulation of the processes that lead, before a certain problem, from the initial and unconscious neuronal response to the final decision that the decision maker presupposes that he has meditated and adopted rationally. The research has barely cleared the path that follows the manager's thought, since he perceives the need to make a decision in a certain situation, until finally adopting it after following a process that, in his / her inner heart, presupposes that it is rational. Does the unconscious neuronal impulse always prevail? Can an informed decision maker control that impulse and decide objectively? These are critical issues that are still ajar.

Much more qualitative study is needed at the observation level of the decision-making processes of the strategic actors, in a controlled environment of their neural records, to collect information about their guidelines. This research should be developed both on individuals at times of individual decision and when participating in group decisions. It will be possible to contrast the characteristics and differences between the strategic decisions taken by the top managers of the organizations alone, and those that arise from interactive processes in boards and management teams. The analysis of the differences between both contexts could shed much light on how the weights of neuronal impulses vary due to the exchange of information, the debate process and the influence of the biology of other debaters, which take place in decision scenarios inside of expert groups in top-level management.

FUTURE RESEARCH DIRECTIONS

The expectation is that neuroscience will enable us to identify the neurological obstacles to change, creativity and innovation. Each region of the brain has a role that affects behaviour differently, and understanding them will help break down the common myths associated with these three functions. Laureiro-Martínez et al. (2014) have gone some way in this direction by studying the cognitive processes

and brain areas that allow decision-makers to switch between exploitation and exploration alternatives, finding different patterns. The regions of the brain associated with exploitation are those linked to the search for rewards, and tracking and evaluating current options. Conversely, exploration relies on the brain regions associated with controlling attention and seeking out alternative options. A comparison of the decisions made by entrepreneurs and by managers also allowed the authors to identify a neuronal trait characteristic of entrepreneurs, appearing in the frontopolar cortex, a key region for exploratory choices.

CONCLUSION

The dialogue between neuroscientific knowledge and technological developments offers up remarkable possibilities for advancing the analysis, explanation and prediction of people's behaviour and thereby developing smarter strategies that draw on the best current understanding of the functioning of the nervous system and genetics. The knowledge contributed by organizational cognitive neuroscience can help academics and practitioners better understand the biological mechanisms—whether physical or neural—that mediate the choice in decision-making, and to break down the decision into its components (Butler et al., 2016). Over the longer term, it will also help to develop models that can better predict decisions.

The extension of neuroscientific research can also support theoretical-practical research in disciplines clearly applied to improving the effectiveness of organizations and their management, such as strategic management. In light of this convergence of knowledge, **neurostrategy** has flourished as a promising field of work.

Nonetheless, it is essential to remain cautious about how the results of neuroscientific research can be applied ethically to today's organizational management. In particular, we must carefully handle the reductionism entailed in identifying the basic neuronal-level mechanisms and raising their explanatory capacity to higher level organizational phenomena, such as how inspiring leaders are identified and developed (Lindebaum & Zundel, 2013).

KEY TERMS AND DEFINITIONS

Behavioural Cognitive Neuroscience: Interdisciplinary field bringing together neuroscientists, economists and psychologists, applying behavioural neuroscience theories and methods to the organizational field, mainly to understand the biological underpinnings of decision-making.

Behavioural Economics: A field dedicated to the study of non-rational choice behaviour and its impact on human health and well-being. The principal differences between this and the dominant economic paradigm is that it takes into account irrationality and environmental influences on the dynamics of choice behaviour.

Bounded Rationality: Paradigm that explains agents' strategic decision-making based on the imperfect information available to them and the expectations they have that dictate whether they will view the results as satisfactory. It leads on to the idea of adaptive learning and trial-and-error processes.

Cognitive Biases: These are irrational prejudices that appear in economic and financial decisions, which influence individuals' decision-making preferences. They include loss aversion, sunk cost fallacy or reward discounting.

Neuromanagement: Scientific field that relies on organizational cognitive neuroscience and technology to explore the brain activity and mental processes involved when people face typical management problems, such as decision-making, as well as other key social behaviours in organizations such as leadership or teamwork.

Neurostrategy: This is the discipline dedicated to uncovering the process of formulating and implementing an organization's strategy, by examining the biological determinants of the functioning of the strategy-maker's brain.

Prospect Theory: The central postulate of this approach, proposed by Kahneman and Tversky, is that, in conditions of uncertainty, people do not make decisions based on the probability of greater gains but rather guided by a series of heuristics.

ENDNOTE

INTRODUCTION

Design thinking is a methodology for proposing creative and innovative solutions for problems that use the mindset of the designers (IDEO, 2019). The Bootcamp Bootleg (Doorley, Holcomb, Klebahn, Segovia & Utley, 2018), produced at Stanford University, suggests the following steps for design thinking: empathize, define, ideate, prototype, and test.

Corporate training usually aims to develop critical analytical skills and competencies, such as analytical thinking, decision making, problem-solving, leadership, and strategic thinking. However, 21st-century holistic and intuitive skills are also required in management today, such as communication, creativity, innovation, and empathy.

Design thinking roots are business and design, and its application to the area of education is recent. Scheer, Noweski and Meinel (2012), for example, claim that John Dewey's ideas are not enough to overcome the difficulties of teaching complex phenomena in a holistic and constructivist way. They compare the methodology proposed by Dewey to design thinking, arguing that the latter can offer concrete recommendations to approach a complex phenomenon without the excess of abstractions.

The objective of this chapter is to discuss how design thinking, combined with information and communication technologies (ICTs), can be used to promote 21st-century skills and competencies in the corporate environment.

No previous literature review on the subject was identified. A literature review was conducted following Okoli's (2015) guidelines for a standalone systematic literature review, including eight steps: identify the purpose, draft protocol and train the team (two scholars), apply practical screen (screening for inclusion), search for literature, extract data, appraise quality (screening for exclusion), synthesize studies (analysis), and write the review.

Google Scholar was the database used for the search. The choice for a single database is justified by results such as those presented by Harzing and Alakangas (2016), who compared Google Scholar with two other recognized databases: Scopus and Web of Science. The authors concluded that all three offer stability and enough search coverage, but Google Scholar outperforms others by criteria such as the number and growth of publications, and the number of citations, thus providing more comprehensive coverage.

The query for the search was:

competencies OR competences OR skills OR skill "Design Thinking"

The search was conducted on August 14, 2018, with 42 initial results. Four titles were repeated and five unavailable. All the 33 remaining texts were included in a Google Drive Sheet, where the data

DOI: 10.4018/978-1-7998-3473-1.ch130

extraction was performed. Coding and categorizing followed the competences and skills frameworks indicated in this chapter.

BACKGROUND

After the 1990s, the world entered a new phase of globalization. For Grundke, Jamet, Kalamova, Keslair and Squicciarini (2017), information and communication technologies, trade liberalization, and lower transportation costs have enabled companies and countries to segment the production process into global value chains (GVCs). Various products are designed in one country, but assembled in another country, from parts manufactured in several countries. Thus, 30% of the value of OECD (Organization for Economic Cooperation and Development) exports comes from abroad.

According to Ismail (2014), the average life of an S&P company fell from 67 years a century ago to only 15 years in 2014, and 40% of Fortune 500 companies would cease to exist in 10 years. Competition from many of the US Fortune 500 companies is not coming from China and India but a new generation of organizations leveraging exponentially growing technologies. Moore's Law and Kurzweil's Law of Accelerated Returns can explain the constant and extraordinary pace of change that organizations are facing today (Ismail, 2014). These changes lead to the challenge of dealing with ill-structured problems (Simon, 1973).

Innovation considered a source of differentiation and competitive advantage in the increasingly complex and rapidly changing business environment of the 21st-century can determine the survival of a project or business (Lee & Benza, 2015). Companies increasingly believe in innovation for their success in the ever-changing business environment.

In today's business context, CGVs and skills are more closely interrelated than ever before. Skills play a crucial role in determining the comparative advantages of countries in CGVs. Many of the opportunities and challenges brought about by CGVs are being affected by country skills (Grundke et al., 2017).

Considering current development processes in society and economics, there is a need for educational systems to prepare young people with new skills and competences that will enable them, in addition to benefiting from emerging new forms of socialization, to actively contribute to economic development under a system in which the principal asset is knowledge (Ananiadou & Claro, 2009).

Organizations that have corporate education structures historically offer developmental actions geared toward critical skills and competences related to the left brain that deals with logic and objectivity. Due to the new phase of globalization and the importance of innovation in business, the skills and competences related to the right hemisphere of the brain, such as holistic thinking, creativity, intuitive thinking and innovation are the objects of attention of business education professionals.

Lee and Benza (2015) report that educational institutions and programs of various types and sizes have successfully incorporated design thinking to foster innovative leadership education, and firms such as Apple and IDEO have demonstrated how it can improve business results. According to Wagner (2012), there seems to be a similarity between innovation skills and the essential elements of design thinking, such as empathy, listening, collaboration and experimentation.

The impact of ICTs on all dimensions of human existence, including the teaching-learning process, is undeniable. The internet, social networks and educational technologies are part of the educational process and the development of professionals. The value added to the Internet and information technologies is not attributed to their existence in the classroom or their characteristics, but to the way they are applied in education (Gebre, Saroyan & Bracewell, 2014; Kim & Reeves, 2007).

According to Kay (2014), Internet and web-based learning tools have a positive impact on teacher and student attitudes as well as student learning outcomes. Researchers have shown that the leading cause of the improvement is not the Internet itself, but rather the increase in the time spent studying online that Internet use for educational purposes can lead to (Tsai, 2015).

DESIGN THINKING APPLIED TO DEVELOP 21ST-CENTURY SKILLS

21st-century Skills

There is a widely shared belief among teachers, educators, policymakers, politicians, and employers regarding the importance of 21st-century skills teaching and assessment (Noweski et al., 2012). It is believed that the present century requires a very different set of people's skills and competences to be able to deal with the challenges of life as citizens, at work and leisure (Pink, 2006; Wagner, 2010; Noweski et al., 2012).

According to Grundke et al. (2017), globalization and modernization are creating an increasingly diverse and interconnected world. To make sense and function correctly in this world, individuals need, for example, to master technological change and understand the vast amounts of information available. They also need to address the collective challenges of society, such as the balance between economic growth and environmental sustainability and prosperity with social equity. From the purely economic point of view, individuals' skills are vital because they contribute to boosting productivity and market competitiveness, minimize unemployment through the development of an adaptive and skilled workforce and create an environment for innovation in a world dominated by global competition.

Several organizations have developed frameworks for competencies and skills for the 21st-century, such as Partnership for 21st Century Skills, EnGauge Framework, 21st century skills and competences for millennium learners (OECD), and Assessment and Teaching of 21st Century Skills. DigComp 2.0 (Vuorikari, Punie, Gomez, & Bran), for instance, identifies critical components of digital competence. DigComp into action (Kluzer & Priego, 2018), by its turn, presents examples and case studies on the framework application. The Basque Government, for example, launched the Ikanos project in 2012 based on DigComp to develop digital competence within the Basque society. Ikanos aimed to address digital competence needs of citizens, enterprises, teachers and other segments of the Basque society. Workshops were organized to disseminate the role of digital technology in education, certification, and the creation of new digital professional profiles. Ikanos project intended to provide support to individuals and organizations to encourage collaboration, explore, share and disseminate digital competences. The project also focused on the definition and development of professional digital competence profiles related to industry 4.0.

Wagner (2010) states that there are seven survival skills for careers, faculty, and citizenship: critical thinking and problem-solving; the collaboration between networks and leading by influence; agility and adaptability; and initiative and entrepreneurship; effective oral and written communication; access and analysis of information; curiosity and imagination. For Himmelmann (2005), the psychological categorization of competences is divided into cognitive abilities; moral and affective attitudes; and practical and instrumental skills. Additionally, Himmelmann (2005) warns of the emphasis that the American and German school systems provide on the measurement and comparison of cognitive abilities, to the detriment of the other abilities.

Pink (2006), in turn, presents what he calls essential attitudes for professional success and personal fulfilment. He distinguishes skills in design, story, synthesis, empathy, and meaning.

According to a 2002 United Nations survey, UNIDO Competencies, some of the skills required for management are: analytical thinking, decision making, troubleshooting, guidance for achievement, organizational knowledge, results orientation, customer orientation, leadership, and strategic thinking (Agarwal & Salunkhe, 2012). Most of these skills refer to the left hemisphere of the brain, responsible for logical reasoning, sequential, rational and analytical thinking. However, the authors argue that it is becoming increasingly important for individuals in the new age to stimulate the right hemisphere of the brain, responsible for skills called: creative thinking, design thinking and innovative thinking.

For Lee & Benza (2015), innovation is recognized as a critical strategic capability in business today. Students and professionals need to be better prepared with innovation skills to meet not only 21st-century requirements in the workplace but also succeed in the careers of their choice. Jobst, Endrejat and Meinel (2001) relate five essential skills that help to train innovative people and are essential for problem-solving and the development of innovations in society: open-mindedness, empathy, T-shaping, dealing with ambiguity, and creative confidence.

According to Hoidn and Kärkkäinen (2014), three overlapping skillsets for innovation are required: technical skills, reasoning and creativity skills, and social and behavioral skills. The last two skills are related to social skills that are grounded in individuals' attitudinal and personal qualities, such as open-mindedness, self-confidence, communication, and collaboration.

Design Thinking

Considering the complexity, speed and ambiguity of the business environment of the 21st-century, and the pressure that professionals undergo to remain relevant, educators seek pedagogical methodologies that help students develop the skills needed to become innovative professionals of the future (Lee & Benza, 2015). More and more, what differentiates a professional prepared for the challenges of the 21st-century work environment are the skills of innovation.

Several experts share the belief that most people can become more creative and innovative if appropriate opportunities and the appropriate environment are offered (Wagner, 2012; Sherman, 2011; Hoidn & Kärkkäinen, 2014; Lee & Benza 2015). However, despite the importance of developing innovative skills, recognized by both employers and educators, most corporate education programs do not seem to offer these skills (Lee & Benza 2015).

Design thinking, according to Brown (2018), is an approach to innovation, practical and widely accessible, that can be integrated into all aspects of a business. Individuals and teams can use it to generate innovative ideas that are implemented to make a difference. It can be described as a set of principles that can be applied by diverse people to a wide variety of problems and organizations. According to Brown (2018), "the mission of design thinking is to translate observations into insights, and these into products and services to improve people's lives." The bridges of insight are specially constructed through empathy, the capacity to try to see the world through the eyes of other people, to understand and feel the world through their experiences and emotions.

The five "modes" or design thinking components can be identified in the toolkit and methods developed by Doorley et al. (2018) from Stanford University's d.School through D.SCHOOL BOOTLEG DECK. They are:

- Empathize: the basis of human-centered design. This mode involves actions: observing, engaging and immersing (putting yourself in the user's shoes).
- Define: when discoveries identified through empathy mode are transformed into needs, insights, and a significant challenge.
- Idea: when radical design alternatives are generated, when possibilities for solutions to identified needs, insights and challenges are explored. Actions involved: innovating, thinking "out of the box," exploring unexpected areas of exploration, flexibility to act with focus and think creatively.
- Prototyping: when, from the creation of prototypes, ideas are transformed into something concrete, to allow the design team thinkers, the user and others to experience and interact.
- Test: when, from prototype testing, the design thinker gathers feedback from users to refine the solutions.

Design thinking combines, briefly, empathy with the context of a problem, creativity in generating insights and collaborations, and rationality in analyzing and adapting various solutions to the context of the problem presented (Lee & Benza, 2015).

The design thinking characteristics make this approach effective in developing empathy skills, as it uses human-centered observation to develop products, services and strategies in its process. Its circular process - establishing empathic relationships, ideation, prototyping, testing, and refinement - encourages students and practitioners to engage with the open mind, ensuring empathy and unexpected discoveries (Lee & Benza, 2015).

Dealing with severe multidimensional problems that do not have recognizable requirements and solutions is one of the most common uses of design thinking. Design problems are mostly ill-structured, and design thinking uses the strategy of problem decomposition to solve it (Ho, 2001). Design thinking was used successfully, for example, to address wicked problems and develop responsible innovation in the French financial industry (Pavie & Carthy, 2014). Innovation emerges in the process of problem-solving through the combination of empathy, creativity, and analysis. This process uses our ability to be intuitive, to discover patterns, and to construct ideas that are meaningful and functional (Fabri, 2015; Shu-Ling & Hui-Lan, 2017).

In this paper, we present the results of a study conducted with several major actors from the French financial industry, which aimed at developing a process for developing responsible innovations by deploying a Design Thinking method. We begin by presenting the context for the study, which includes a brief description of our approach for understanding and exploring the issues raised by responsible innovation. This first part also includes a comparative analysis of the characteristics of RI (responsible innovation) and wicked problems in order to establish a potential link between the two concepts. Secondly, the Design Thinking method is introduced as a potentially suitable approach for addressing wicked problems and thus, RI. Finally, the process for developing responsible products and services which was developed throughout the study is presented.

Design thinking is not a linear process (convergent thinking) that follows step-by-step procedures, but a process of discovering connections (divergent thinking) to see new patterns and possible relationships that exist in your school, even though both types of thinking are needed within all types of organizations (Gould, 2018).

As practitioners increasingly embrace design thinking to achieve innovation, corporate education professionals have begun integrating design thinking into business curricula to enhance students' creative skills (Schiele & Chen, 2018).

Design thinking stimulates and develops a mindset that seems to meet 21st-century demand. A design thinker uses all his senses and analytical and creative skills to develop activities. When, for example, he/she goes on the field, establishes dialogues with different stakeholders in the solution, observes and genuinely knows the world of another person, puts himself/herself in the other person's place, and collaboration with other colleagues, creates possible solutions (Noweski et al., 2012).

Active Learning Methodologies

Learning is understood by constructivism as a personal process of meaning-making, in which the individual assimilates information, relates it to the knowledge already possessed, and processes it cognitively. Constructivist teachers work on students' development through reflection, analysis, and gradual construction of knowledge through the conscious and permanent mental process mediated by experience (Fabri, 2015). Designing is aligned with the principles of constructivism, in which learning is primarily understood as a social process, which requires interaction between participants, facilitators and others (Noweski et al., 2012).

Lee & Benza (2015) reports that several suggestions have been made regarding methods and tools that enhance the development of innovation skills, such as problem-solving, critical thinking, and collaboration. Project-based learning (Markham, 2013) and problem-based learning (Hoidn & Kärkkäinen, 2014) are student-centered methods and can improve the development of innovation skills as students benefit from direct involvement in problem-solving. However, the design thinking approach is, in comparison to these methodologies, admittedly the most inclusive because it covers the process, tools and experiences of the project in solving innovative problems (Brown, 2008; Liedtka, King and Bennett, 2013; Wagner, 2012; Coakley, Roberto & Segovis, 2014).

According to Kolb & Kolb (2017), the Theory of Experiential Learning (TAE) seeks to convey the teachings of twentieth-century scholars, especially William James, John Dewey, Kurt Lewin, Jean Piaget, Lev Vygotsky, Carl Jung, Paulo Freire, Carl Rogers and others, who put experience at the center of the learning process and the learner-centered educational system. TAE is a dynamic view of learning based on a learning cycle driven by the resolution of the dual dialectic of action/reflection and experience/abstraction (Kolb & Kolb, 2017). Students learn through their reflexes and their colleagues, necessary for students' metacognitive development. The approach considers a cyclical model with four stages of learning: concrete experience, reflection, abstract conceptualization and active experimentation (Fabri, 2015). The learning cycle is driven by the integration of action and reflection and experience and concept.

According to Kolb and Kolb (2017), TAE is a dynamic and holistic theory of the process of learning from experience and a multidimensional model of adult development. The differential of experiential learning lies in the unique relationship created between the teacher, the learner, and the subject under study. The experiential approach puts the subject to be learned at the heart of the process. Both the educator and the learner experience the subject. According to the learning cycle, all participants receive from the subject information through concrete experience and transform it through reflection and conceptualization, and then transform it again, including what information has been served with the new experience. Both the teacher and the student are receivers of information and creators of information. This process promotes a levelling effect on relationships, as all can directly experience the subject (Kolb & Kolb, 2017).

According to Rauth, Köppen, Jobst and Meinel (2010), design processes and thinking can be seen in analogy with learning concepts of the Experiential Learning Theory, considering its cyclic vision of learning.

Design Thinking Applied to Corporate Education

Through the literature review, it was possible to identify empirical research, guided by different theoretical references, that have been carried out in several countries to evaluate the relationships between the skills and competences of professionals with the design thinking approach. We present two of the analyzed researches, chosen because although the institutions had a similar objective, that is, to evaluate the impact of design thinking on the skills and competences of the students, the target audience of the researches had different characteristics and were carried out in different cultures and countries.

Lee & Benza (2015) present an experience in which the design thinking method was adopted as a pedagogical approach for teaching the MBA course in Innovative Brand Management at California State University / United States of America. The course, which lasted 10 weeks, aimed to: 1) equip MBA students with a design thinking toolkit; 2) help them use the tools; 3) teach students how these principles could create innovative brands. The course utilized small-scale replication materials, the Stanford d.School prototyping approach to design thinking and used texts that presented a real-world design thinking case study approach (e.g., IBM, 3M, Toyota, Intuit, and SAP). These texts were previously read at home to conduct the discussion in the classroom. Students evaluated the course in two ways. The first assessment consisted of analyzing the scope of the program's objectives, according to its perception, on a scale of 1 to 5 points. Instructors also completed this assessment, which made it possible to compare students and instructors' perceptions. The students had a second evaluation consisting of drawing up a list of the three most important lessons learned in the course. The authors stated that students realized that the course helped them achieve all goals with high grades. Regarding the most important lessons learned, the students highlighted: development of 'open-mindedness and flexibility' and 'empathy and client orientation' attitudes; 'design thinking as an innovative approach to problem-solving in real life' and 'the importance of collaboration in creative thinking'. The instructors' assessment was like that of students in most learning objectives. However, they argued that the limited time available negatively affected the results of the use of the power of coaching to understand their audience in the development of compelling stories.

Agarwal & Salunkhe (2012) present the results at the Welingkar Institute of Management, an essential Indian business school in Mumbai, with the introduction of a new graduate management course called the Business Design Program. The new program had curriculum and pedagogy as differentials over conventional management programs. The curriculum presented a holistic structure focused on integrating the knowledge of the different areas of study, in addition to the disciplines related to the right side of the brain. The pedagogy adopted in the new program involved: 1) the availability of two laboratories ("Innowe Lab" and "Design Workshop") on the Welingkar's campus to support experimentation and prototyping activities; 2) experiential learning, through rural projects; 3) practical learning, through experiential projects; 4) integrative thinking. A group of 60 students were exposed to the Business Design program for one year. The treatment group had their results compared to the results of a control group, i.e. students who were exposed to the normal course of management. The results obtained in the regular management skills, or conventional, the results of the right brain competences, that is, creative thinking, design thinking and innovation were defined as success criteria of the experiment. The data were collected from the application of a self-assessment questionnaire to the students of both groups. The results showed there no significant difference between the treatment and control groups regarding the skills and abilities related to the left side of the brain, such as decision making, analytical thinking, results orientation, organizational awareness, adaptability, client centricity, leadership, teamwork, achievement orientation and strategic thinking. However, it was possible to identify a significant difference in

the competences “creative thinking” and “thinking of design” between two groups. The mean values of “creative thinking” and “design thinking” were significantly higher in the treatment group compared to the control group.

ICT Support for Design Thinking

In the Laser Serious Courses program, a course called Practice of Engineering Skill (Shu-Ling & Hui-Lan, 2017) was developed at the School of Science Instrument and Opto-electronics Engineering (Beihang University, Beijing, China). The authors Shu-Ling & Hui-Lan (2017) state that all students and teachers have a preferred learning style and teachers teach in the way they learn. Design thinking is understood as an effective method to resolve this incompatibility. In the Beihang University program, technology is used to facilitate content delivery, as there are several ways students can access knowledge. The lecture is not essential for the delivery of content. Students, in turn, prefer courses that have online components, such as: collaborate in online discussions, conduct online research and prepare to participate in the classroom discussions of concepts previously studied.

Tsai (2015) in a quasi-experiment with 153 undergraduates, who participated in the course “Applied Information Technology: Data Processing”, reports that web-based design thinking was adopted to help students focus and study in a blended computing course and explore its effects on improving students’ computing skills. According to Lee & Choi (2011), in today’s crowded online entertainment environment, students’ inability to self-regulate learning is likely to be one of the reasons for high drop-out rates in distance learning courses. Self-regulation of learning is more critical in the context of distance learning than in a traditional context, due to the electronic, social and self-directed nature of online learning. In the quasi-experiment with undergraduate students, Moodle was used as the learning management system for all students, aiming to share useful information, documentation and knowledge management. Considering the various tasks suggested to participants, which involve forms of collaborative learning, there may also be potential to investigate the effects of co-regulated learning (Tsai, 2015).

SOLUTIONS AND RECOMMENDATIONS

As the literature review demonstrated, in the current state of research, there are still few studies on the use of design thinking to develop corporate skills and competencies. The empirical articles identified usually explore the use of design thinking in formal and academic teaching environments.

However, design thinking theoretical background has a direct relationship to what is called the 21st-century skills for work. In this sense, more research is needed with the focus on exploring the use of design thinking in corporate training.

Besides that, the use of technology in education, in general, seems to foster active teaching and learning methodologies. These methodologies, and particularly design thinking, should then be combined with the use of new technologies both in academic and corporate education.

FUTURE RESEARCH DIRECTIONS

Some researchers, whose work was read in this literature review, presented some tools, tests or categorizations to support their studies. Noweski, et al. (2005), chose to work with the psychological categorization

of competences offered by Himmelmann (2005), which classifies the main competences in: cognitive abilities, moral and affective attitudes, and practical and instrumental skills, and used ISK tool (ISK 2009) to map participants' basic social skills.

According to Shu-Ling & Hui-Lan (2017), students capture and process information in different ways, such as viewing and listening, reflecting and acting, reasoning logically and intuitively, analyzing and visualizing, intermittently. The teaching methodologies do not also vary with the multisensory forms of information processing. In the teaching-learning process, both teachers and students are subject to education. The teachers' 'understanding of the students' learning methods is strategic for facilitating the process.

As students and practitioners have different behavioral and cognitive characteristics, and this may affect the results of applying the design thinking approach as teaching-learning methodology, additional experimental studies on learning profiles and identification of skills students can contribute to the effectiveness of the 21st-century skills and competences development process.

The use of information and communication technologies is present in school environments, in the education of executives and organizations. However, through the reading of the selected articles, we have identified an opportunity to deepen theoretical and experimental research on the use of ICTs in supporting the development of the skills of 21st-century professionals, in design thinking initiatives and professional education. Considering the importance that the skills and abilities of collaboration and communication have in the process of searching for innovative solutions and in the expansion of the repertoire of learning of professionals, ICTs through tools such as forums, communities of practice, and virtual rooms can positively support several of the steps in the design thinking approach.

CONCLUSION

The current emphasis on the development of so-called soft skills, or the skills and competences of the 21st-century and its impacts on business, has been widely presented in the literature studied in this chapter.

Without innovation, there is no progress, and without creative and skilled people who can meet future demands, there is no innovation. Therefore, innovators of the future, both social and professional, need to be equipped with 21st-century skills (Carroll et al., 2010).

The design thinking characteristics make this approach effective in developing empathy skills, as it uses human-centered observation to develop products, services and strategies in its process. Its circular process - establishing empathic relationships, ideation, prototyping, testing, and refinement - encourages students and practitioners to engage with the open mind, ensuring empathy and unexpected discoveries (Lee & Benza, 2015).

The results presented by several field researches in the studied literature, reflected by the experience of students, professionals and instructors, reveal that the approach of design thinking, applied as a teaching-learning methodology experienced, is effective in sensitizing and teaching the students and professionals toward a range of essential skills and competences needed by 21st-century professionals such as empathy, creative problem-solving, collaboration, open-mindedness and communication. The ICTs, in turn, is a support for this enterprise.

KEY TERMS AND DEFINITIONS

Co-Regulated Learning (CRL): Co-regulated learning (CoRL) refers to the coordination of the process of self-regulation through self-interactions.

Comparative Advantages: The concept of comparative advantages explains why trade between two countries, regions or people can be beneficial, even when one of them is more productive in the manufacture of all goods. What matters is the productivity ratio that each country has. Even if a country does not have an absolute advantage, it can specialize in those sectors where it has a comparative advantage.

Integrative Thinking: It is a type of thinking that gets involved with the problem differently from the conventional one. Integrative thinkers strive to keep the whole problem in mind as they work on individual parts, unlike the conventional ones that try to deal with the elements individually or sequentially.

ISK (Inventar Sozialer Kompetenzer): Is a comprehensive, multidimensional self-assessment tool that maps basic social skills (<https://www.testzentrale.de/shop/test-komplett-bestehend-aus-manual-20-fragebogen-isk-20-fragebogen-isk-k-20-auswertungsbogen-isk-20-auswertungsbogen-isk-k-20-profilblatt-isk-20-profilblatt-isk-kup-kanning-diagnostik-sozialer-kompetenzen-und-box.html>).

Law of Accelerated Returns: For Kurzweil, through the Law of Accelerated Returns, the pattern of duplication expressed in Moore's Law would apply to any information technology, being the propellant of this phenomenon, the information.

Moore's Law: The price/performance ratio of computing would double every 18 months in the case of semiconductor circuits.

Self-Regulated Learning (SRL): Involves the effort of a student to manage and evaluate their learning processes. It is also considered one of the most important skills needed for lifelong learning.

Managerial Challenges of Corporate Social Responsibility in Developing Countries

INTRODUCTION

There has been a growing interest in the adoption of corporate social responsibility (CSR) practices in the advanced Western and developed Asian and emerging countries over the past several decades (Crane et al., 2019; Carroll, 1999; Carroll, 2016; Davidson & Yin, 2019; Fukukawa & Teramoto, 2009; Jamali, 2007; Matten & Moon, 2008). Such a massive amount of attention to CSR practices is largely attributed to its potential business benefits such as increased retention and reduced recruitment and training costs (Bhattacharya et al., 2008), simultaneous achievement of the triple bottom-line measures (i.e. people, plant, profit) (Kanji & Chopra, 2010; The Economist, 2009), favourable image, reputation, and customer retention (Eisingerich & Ghardwaj, 2011; Korschun et al., 2011), effective risk management (Kytte & Singh, 2005), brand differentiation, and a platform to engage with a diverse range of stakeholders (Lai et al., 2010 – see also Carroll & Shabana, 2010; Epstein, 2018; Luo et al., 2015). It has to be recognised, however, that the full realization of the potential benefits of CSR hinges, in the main, upon managerial orientation and attitude towards CSR practices. This importance is essentially that of Agle et al. (1999), Finkelstein & Hambrick (1996), Jamali et al. (2008), Pant & Lachman (1998), Quazi & O'Brien (2000) and Waldman et al. (2006) who lay stress on managerial personal values as prime factor in firm's engagement in CSR on both performance and ethical grounds (Donaldson & Preston, 1995; Duarte, 2010; Galbreath, 2010; Hemingway & MacLagan, 2004; Petrenko et al., 2016). Despite the acknowledged significance of CSR practice as a catalyst for enhanced perceptions of organizational performance and individual ethics in both advanced industrialized countries and emerging market economies (see Trajkova et al., 2018) the nature, extent and intricacies of CSR *Management* in the developing countries (e.g. Middle East region) has remained comparatively unresearched (Blowfield, 2007; Blowfield & Frynas, 2005; Jamali, 2007; Jamali & Karam, 2018).

In recognition of this lacuna of empirical research in the CSR management literature pertaining to the developing countries, this chapter aims to explore the peculiarities of CSR management and whether it is perceived the same way as is adopted and adapted by advanced industrialized countries and emerg-

DOI: 10.4018/978-1-7998-3473-1.ch131

ing market economies (Dikeç et al., 2019; Eweje & Sakaki, 2015; Steurer et al., 2012; Visser, 2008).). The need for a critical analysis of CSR management in developing economies gives weight to different socio-cultural, economic, religious, individual and organisational backgrounds of managers. Indeed, CSR scholars have long acknowledged the idea that socio-economic, cultural and religious characteristics of managers are expected to affect their attitude and orientation as well as subsequent behaviour and actions towards CSR (see Darrag & E-Bassiouny, 2013; Goby & Nickerson, 2016; Jamali, 2014; Jamali & Karam, 2018; Quazi, 2003; Quazi & O'Brien, 2000; Wood, 1991; Waldman et al., 2006). This is in particular the case for developing Muslim-majority countries of the Middle East region where Islamic law (or the sharia) assumes a broader and more holistic significance for both individuals and business firms. In contrast to perceived strategic and instrumental nature of CSR in Western societies for enhancing goodwill or boosting long-term financial performance (Garriga & Mele, 2004; Windsor, 2001), corporations in Islamic societies assume the roles and responsibilities as servants and vicegerents in all situations responsible towards and ultimately responsible to God. In doing so, they view CSR as a moral and religious and obligatory initiative based on the belief that they should act in the interest of the society as a whole regardless of its financial consequences (Ahmad, 2003; Dusuki, 2008, pp. 18). Despite voluntary CSR decisions of Western organisations, performing socially responsible activities are deemed obligatory in Islamic business context (Mir et al., 2016). Thus, this chapter unravels the nature of managerial CSR attitudes and orientations in the Middle East region (Payind & McClimans, 2017) with a focus on Iran's auto industry (The Economist, 2019).

This chapter is divided into four main sections. The first section provides a review of the literature on CSR management. The second section discusses the research design and context of the study. The third section presents the findings derived from qualitative data collected from different several manufacturing firms operating in Iran's automotive industry. We finally conclude the chapter by highlighting avenues for future research.

THEORETICAL BACKGROUND OF THE STUDY

Research into managing CSR practices has evolved in different directions and caused widespread controversy among organizational scholars. This ranges from viewing CSR as a business-centred and instrumental model (Gond & Matten, 2007, pp.1) to conceptualizing the inherent nature of societally embedded CSR (Gond & Matten, 2007, pp.1). Despite the existence of competing and contrasting perspectives of CSR and resulting multiple conceptualizations of the term, we categorize CSR management research into two broad streams: (i) research into the quest for CSR; and (ii) studies of the relevance and appropriateness of managerial attitudes and orientations toward CSR (e.g. Hillman & Keim, 2001; Howell & Avolio, 1992; Jones, 1995; Kanungo, 2001; Waldman et al., 2004).

The central theme of research into the quest for CSR has focused on a number of competing and contrasting theoretical traditions. Following Wood's (1991) multilevel analysis of CSR research, we discuss the quest for CSR practices from institutional, organizational and individual perspectives. The institutional level analysis places organizational legitimacy at the core of a quest for CSR. This debate was first stimulated by the contribution of Davis (1973) who coined the phrase 'Iron Law of Responsibility' to express legitimacy as a societal level concept. As she put it, "Society grants legitimacy and power to business. In the long-run, those who do not use power in a manner which society considers responsible will tend to lose it" (1973, p. 314). Those who view the principle of legitimacy as the rationale underpinning the CSR practice describe the responsibility of business as a social institution that

must avoid abusing its power. As a societal-level concept, legitimacy connotes a prohibition rather than an affirmative duty which applies equally to all companies. Studies advocating a legitimacy approach further explore the theoretical underpinnings of this principle in terms of functional theory (Preston & Post, 1975), stakeholder perspective (Freeman, 1984), and utilitarian theory (Clark, 1916). At the organizational level, the focus is on the sensitivity and paramount importance of public responsibility. Derived from the work of Preston and Post (1975, p. 10), the principle of public responsibility refers to “the functions of organizational management within the specific context of public policy”. According to this principle, the organization’s quest for CSR is seen to solve any social issues arising from their business operations. These include both areas of primary involvement with society which arises directly from the firm’s specialized functional role and secondary involvement with society which is a function of the primary behaviours and transactions. To better operationalize this principle, Wood (1991, p. 698) translates public responsibility into a broader ‘rule of relevance: the reciprocal influences of business and society’. At the individual level, the central theme of discourses on CSR has put the stress on the idea of ‘managerial discretion’ (Ackermann, 1975). A clear expression of this principle is echoed by Wood’s (1991, p. 698) comment that “managers are moral actors. Within every domain of corporate social responsibility, they are obliged to exercise such discretion as is available to them, toward socially responsible outcomes”. Of paramount concern for Wood (1990) is how a company fulfils its voluntary or compliance-based CSR mandates. Her central line of argument is worth quoting: “A company’s social responsibilities are not met by some abstract organizational actors; they are met by individual human actors who constantly make decisions and choices, some big and some small, some minor and other of great consequence” (cited in Wood, 1991, p. 699).

As is evident from the review of research into the quest for CSR, institutional and organizational quests for CSR practices rely, in the main, upon varying perceptions and orientations of individual managers to pursue CSR decisions and strategies. Studies of the relevance and appropriateness of managerial orientations towards CSR (e.g. Hillman & Keim, 2001; Howell and Avolio, 1992; Jones, 1995; Kanungo, 2001; Waldman et al., 2004) have highlighted the paramount importance of personal attitudes and orientations as forces that shape managerial decisions and subsequent actions (Triandis, 1995; Waldman et al., 2006). The hypothesised importance of managerial attitudes and orientations in the context of CSR is largely attributed to the ‘multidimensionality of CSR values’ (Freeman, 1984). This is the position taken by the proponents of ‘stakeholder theory’ who view a firm to consist of a variety of different constituencies and that each constituent has a strategic and/or moral stake in the firm. Given such variety of different constituencies, it is no surprise to observe that each constituent advocates its own interests and values (Donaldson & Preston, 1995; Freeman, 1984, 1994). Waldman et al. (2006, pp. 824; see Wood, 1991) take the argument further with their hypothesised connection between the potential conflicts of interest between stakeholders and their direct influence on the managerial orientation toward CSR. In addition to the ramifications of the conflicting interests of the stakeholders for the way managers perceive choices to pursue CSR decisions, others highlight the paramount importance of various cultural and leadership contexts to play a part in shaping managerial orientation and subsequent actions towards CSR. The influence of these forces (e.g. for national cultural norms of work – see Hofstede 2001; for organisational culture – see Schein, 1992; Vitell & Paolillo, 2004; for profession – see Sirmon & Lane, 2004) is particularly evident in the work of Williams & Aguilera, (2008) and Waldman et al., (2006). The emphasis arising from these cross-cultural studies is not so much the effectiveness of CSR practices or their bottom line performance impact. Rather, It is the compelling evidence that managerial attitudes and orientation toward CSR vary across countries, owing to the myriad of socio-cultural, economic and political forces such as hyper and local norms, social institutional constraints, and the level of industrial-

sation (see Cullen et al., 2004; Donaldson & Dunfee, 1999; Egri et al., 2006; Jamali et al., 2008; Javidan & Dastmalchian, 1998, 2003; Quazi, 2003; Spicer et al., 2004; Storey, 1992; Waldman et al., 2006; for a review see Williams & Aguilera, 2008, pp. 460–465). Although these cross-cultural, country-level analyses have offered some potential in clarifying the hypothesized relationship between managerial orientation and firm-level CSR outcomes, they are fraught with immense difficulty, owing to the vast range of confounding variables and their heavy focus on Western-dominated and emerging economies contexts, thereby devoid of critical analysis of CSR management in non-Western organisational contexts. These studies have therefore failed to allow the progressive refinement of a CSR-oriented management model which delineates the personal attributes and values of senior managers that could influence their orientation, shape their subsequent actions, and determine the propensity of firms to engage in CSR (see Storey, 1992; Waldman et al., 2004).

One way to tease out these unresolved issues in the existing conceptualisation of and theorising CSR-oriented leadership model is to more directly examine the various managerial orientations which could determine the extent to which firms engage in CSR and result in different firm-level CSR outcomes. As Van Tulder & Van der Zwart (2006) have pointed out, the current theorisation of the role of managerial leadership of CSR is primarily concentrated on Anglo-Saxon, Western dominated contexts and this in turn makes it difficult to arrive at general conclusions.

Despite a growing body of research attesting to divergent nature of CSR practices (Jamali et al., 2015) and CSR management as a context-sensitive and -dependent phenomenon (Waldman et al., 2006), research on the actual practice of CSR and managerial leadership of CSR across the developing world has been sparse. Jamali et al.'s (2017) study of the meaning and practice of CSR in four developing countries (i.e. China, India, Nigeria and Lebanon) is suggestive of supranational and culturally embedded and nuanced institutional logics shaping CSR in developing countries. In a similar vein, Chapple and Moon's study of CSR in seven Asian countries (i.e. India, Indonesia, Malaysia, the Philippines, South Korea, Singapore and Thailand) suggests that while CSR does vary considerably among Asian countries, the difference in the actual practice of CSR is less to do with the level of economic and social development. Instead, the actual practice of CSR is a function of the national business systems. In line with these macro-level analysis of CSR adoption and diffusion, other scholars have offered a more micro- and meso-levels account of CSR practice in the developing economies. Rahaman's (2000) qualitative study of Ghanaian firms is suggestive of the reluctance of Ghanaian companies to take a stand on CSR and that they make little or no effort to measure, disclose or even adopt a formal environmental management system. Newson & Deegan's (2002) study of 150 large Australian, Singaporean and South Korean multinational corporations (MNCs) is indicative of paying lip-service to the notion of global expectations of sustainable business practices and that (e.g. non-financial and environmental disclosure policies). At the micro-level of analysis, research evidence places emphasis on the managerial perceptions towards the adoption and diffusion of CSR. In Rahaman et al.'s (2004) examination of CSR adoption motivation in Ghana, managerial interviewees referred to external pressure from international lending organisations such as the World Bank to be the main driving force behind CSR adoption. Belal & Owen (2007) followed a similar line of qualitative inquiry in Bangladesh and found that a desire to manage powerful stakeholder groups to be the main logic CSR adoption and implementation by Bangladeshi managers (see also Islam & Deegan, 2008; see for a review Belal & Momin, 2009; Goby & Nickerson, 2016; Jamali & Karam, 2018; Soltani et al., 2015).

As is evident from the above summary of CSR research in the context of developing economies, the developing Muslim-dominant region of the Middle East has received less attention than it deserves (see Payind & McClimans, 2017). This inattention is despite the fact that the region plays a major role

in global economics and politics and that Islamic law (the sharia) and institutions play a major role in shaping the nature and scope of social imperatives and consequences of business success. The Islamic law requires people to submit to the Sharia by committing themselves to the contractual obligation and leading life in accordance with high virtue and moral consciousness. More specifically, sharia assumes a more vital role than the social contract for both individuals and businesses (pp. 14). While neoclassical economics expect individuals and businesses to conduct economic, social and other worldly activities as self-centred utility-maximising economic agents, the religious bond expect individuals and businesses to maintain a balance between the rights and responsibilities of the individuals and that of society (Chapra, 1992). The essence of social responsibility in developing Middle East region is firmly inscribed within the religious bond (14). As Dusuki (2008) observes “Islam...envisages business firms as stewards and caretakers, not just o shareholders’ financial resources, but also of society’s economic resources, holding their property in trust for the benefit of society as a whole and ultimately attaining the blessing of God (pp. 22). In contrast to the voluntary and optional nature of CSR policies and practices of corporations in developed economies, CSR is a religious obligation for all Muslims and hence individuals and business firms in Muslim societies are to instil good environmental, occupational, philanthropic, mutually beneficial CSR Initiatives.

While the preceding review of research on CSR adoption in developing economies attributed the effectiveness of CSR practices to a myriad of internal and external factors, the common denominator in the extant literature on CSR appears to be the primacy of management role – as opposed to view the corporation or external constituencies as the agent (Ackermann, 1975; Hemingway & MacLagan, 2004; Matten & Moon, 2008; Wood, 1991). Despite the acknowledged significance of management to strategic and sustainable CSR programmes and long-term CSR success and renewed call for more research Western and emerging contexts (see Jamali & Karam, 2018; Goby & Nickerson, 2016; Soltani et al., 2015), the intricacies of CSR management in organisational adoption and implementation of CSR in the context of developing countries has relatively remained understudied.

The aim of this book chapter is to respond to these challenges and examine the research phenomenon through a qualitative case study of a leading automotive manufacturing group in the Middle East (identified by the pseudonym ‘Safe Car’). The automotive group in the current study has been involved in extensive joint-ventures operations with foreign firms of high CSR profile.

RESEARCH CONTEXT AND DESIGN

As the seventeenth-biggest state in the world and the second-biggest nation in the Middle East, Iran is known as a forward thinking nation in the region. It has a self-sustained automotive industry ready to embrace environmental and transportation challenges (Singh, 2016). The Auto industry is the country’s biggest non-oil industry (with contribution to over 10% of Iran’s GDP) which has grown to be the largest in the Middle East and 12th largest worldwide (Bahar, 2005; Haigh, 2018). A recent report by Organization of Motor Vehicle Manufacturers (OICA) indicates that Iran is the 12th biggest car market on the planet in 2017, with sales in the region of 1.5 million cars. In a bid to build a more competitive automotive industry, the government has sought to seek foreign-invested joint ventures with a particular focus on upgrading technology, protecting the environment, energy efficiency and passenger safety over the past several decades. Since then, its local auto-makers have established joint-ventures with prominent world carmakers with well-established local and global CSR policies (see Economist, 2019; Jamali, 2014).

Given the nature and recent calls for greater understanding of CSR managerial leadership, a qualitative case study approach was adopted (see Eisenhardt 1989; Yin 2003). The adopted case study approach had the potential to flesh out the peculiar CSR management orientations, provide context-dependent knowledge, and capture context-dependent reasoning for various orientations of CSR managerial leadership (Flyvbjerg, 2006; Klenke, 2008).

To collect qualitative data, we focused on ‘Safe Car’ (a pseudonym) Industrial Group. The primary means of data collection was semi-structured interviews with 28 managers at various functional and hierarchical levels. In addition, archival evidence, document analysis, and participation at in-house training sessions on CSR awareness (i.e. methodological triangulation) constituted other sources of the qualitative data. The frequent visits made to the parent company and two of its affiliates with most number of foreign joint ventures by each member of the research team during the course of the study constituted a valid basis for collecting personal or participant observation data. The research team actively took part in both one-off and regular as well as formal and informal in-company CSR-related meetings. They attended all the related workshops sponsored by each firm as well as those of jointly sponsored seminars, which aimed at enhancing intra-firm ethical working relationships.

For the purpose of the analysis of the data, we adopted a ‘discovery oriented approach’ (see Ogbonna & Harris, 2003) in that we, first, identified and named the emerging categories and properties from the data (open coding). Next, we attempted to establish a causal relationship between them (Axial coding). We finally revised, integrated, and refined the categories and properties into a core theory (selective coding) (Glaser & Strauss, 1967; Strauss & Corbin, 1990). Although a single case study can result in analytic generalisation, our aim here is to draw on alternative explanations for the extent to which firms engage in CSR by capturing various managerial orientations and their resulting ramifications for the firm’s CSR strategy.

FINDINGS

Founded in the 1960s, Safe Car Industrial Group (hereafter called ‘*Safe Car*’) is a large state-run enterprise with major interests in the automotive industry (e.g. assembling and manufacturing different types of cars). Safe Car is composed of the parent company, several subsidiaries and affiliates with domestic, regional and international operations. Its activities also embrace a portfolio of products and services, namely, investment in and acquisition of domestic and regional firms, trading and commercial services in collaboration with domestic and international firms and information technology. Although the U.S.-led sanctions on Iran’s auto industry and its associated services (e.g. transportation, insurance) led to a 17% plunge in the sales over the past several years, the operating profit of Safe Car had recently experienced a slow revival as the sanctions lifted (see Financial Times, 2014). Safe Car’s business model put the stress on the idea of ‘joint venture’ with both local and international car manufacturers.

The Nature and Awareness of CSR

The interviewees perceived CSR as a synonym of “self-management”, “self-control” and “self-discipline”. They felt positive about the adoption and diffusion of CSR practices and expressed a firm commitment to gain more familiarity with the complex and multidimensional nature of CSR. Owing to their religious orientations, ‘*sharia*’ (Islamic law) was frequently cited as the fundamental basis for understanding and promoting CSR. Several interviewees talked about *sharia* as the company’s “total CSR package” com-

posing of ‘*aqidah* or belief and faith’, *akhliq* or morality and ethics, and *fiqh* or legal rulings governing the acts of human beings (see Ahmad, 2003; Dusuki, 2008, pp. 14; Sardar et al., 2003; Schacht, 1964, pp.24). In the words of a senior public relation manager, “We follow the teachings of the *Quran* and *Hadith* and *Sunna* as a reliable reference point for our enquiries and needs at both individual and societal levels”. However, a key tendency appeared to be the increased emphasis upon the ‘individual’ rather than ‘collective’ well-being of all stakeholders. As a result, managers were selective in the way they exercised their CSR-driven ideas. Despite some evident diversities in their CSR approach, charitable and philanthropic measures, voluntary community services and corporate-NGO partnership were seen to be common CSR practices across Safe Car. Whilst a majority of the interviewees intended to extend CSR beyond the scope of work-related individual responsibility into the institutional and societal concerns, the level of awareness of how this could happen was rather low. As a human resource director put it, “In theory we are aware of the Islamic CSR and its message for individual employees, managers, organisations and the wider community of stakeholders. But we face challenges to effectively operationalize it. These challenges come from both the institution and the external environment. All we do is to comply with relevant institutional and industry regulations. Of course, this is not what we want but we cannot go beyond that. We all try to take it on-board at least at the individual level. That’s all we can do”.

This set of remarks reveals that whilst managers were intent on forcing CSR out of its silo and onto the management agenda as an organization-level activity, they were rather unable to utilise it as a way of unfreezing the *status quo*. In the light of the institutional and external forces, managers therefore perceived CSR to be an add-on activity and a peripheral to their main responsibilities. Quite clearly, CSR practices were therefore seen to be a priority where they could fulfil their obligatory responsibilities and more importantly the economic interests of the firm.

Triggers to Embrace CSR

The triggers for CSR in Safe Car were attributed to personal/individual, institutional/organisational and external/environmental forces. At the personal level, the respondents were bound by Sharia compliance mandates which govern all aspects of Muslim life. Three primary sources express the essence of the concept: the *Quran* – the Muslim holy book, the *Hadith* – the sayings and conduct of the prophet Muhammad, and *Fatwas* – the rulings of Islamic scholars (Dusuki, 2008; BBC, 2009). Discussion with managers at various hierarchical levels uncovered a generally consistent account of what sharia symbolised. Comments such as “the roadmap”, “the measure of right and wrong”, “the code of conduct for mankind”, “the balance between individual’s and society’s needs” and “the recipe for living a good life both at work and home” were indicative of the importance and ramifications of Sharia compliance. These instances which view Sharia as a set of rules and system of values and proselytise it as of universal applicability reflect the ways and manners in which individual managers utilise the philosophy of sharia to regulate their personal and work-related actions and maintain a good work-life balance.

At the institutional level, managers seemed to go further by indicating potential connections between their personal values with those of organisational and society needs. On the one hand, the need for sharia compliance made explicit a set of guiding principles and a work value system for the whole organisation (which was implicitly held by individual managers). The trigger element in the work value system was the notion of ‘*taqwa*’ (God-consciousness) meaning that “a company should be socially responsible regardless of the financial consequences”. On the other hand, the diffusion of the work value system within the organisation was reported to be entirely dependent on the top management orientation towards CSR. The majority of middle and supervisory level managers hold the view that the ‘vested interests of the top

management team (primarily for, as one HR manager put it, ‘personal stake and interest’) coupled with their ‘narrow focus’ and ‘ambiguous’ understanding of CSR set the tone for the rest of SAFE CAR and the broad community of its stakeholders to perceive CSR as ‘a peripheral add-on activity’ and ‘a mere functional cog in the organizational wheel’. For the interviewees, the CSR mandate at the top management level was highly passive in the spheres of society involvement and environmental sustainability but proactive in the economic and profit-maximisation sphere.

From an external/environmental standpoint, the triggers for embracing CSR were not greatly informed by the notion of triple bottom line – i.e. social, environmental/ecological, financial (see Savitz, 2006). This was partially because CSR was not taken on-board as a business strategy or effectively built into firm strategy. The following are verbatim transcripts of some of the interviewee’s comments on the external forces which trigger firms to embrace CSR: “We have initiated our CSR programmes as a response to external industry pressure in particular with regard to both vehicle and road safety”; “For us CSR programmes have the potential to make our market positioning more competitive in the eyes of the shareholders and in particular the government”; “We have made concerted efforts to increase the production rate in the global market and have active presence in foreign markets. So we need to conform to the global industry accepted pattern of behaviour”. Across the group as a whole, as this set of remarks reveals, there was a definite interest in embracing CSR as a default response to heightened competition, to meet investor expectations, and to fulfil the contractual joint venture agreements with foreign partners (see Bahar, 2005; Dubowitz, 2013).

Characteristics of Management Orientations

The dominant personal values attached to the notion of CSR (as opposed to the strategic value of CSR) resulted in a plethora of different meanings and interpretation of how CSR could be instituted. The analysis of the interviewees’ responses across Safe Car revealed that the CSR initiatives were unilaterally devised by the top management team. This implies that the path of CSR adoption and implementation had not conformed to a coherent and systematic plan with mutually beneficial and reinforcing practices for all stakeholders (Storey, 1992; Storey et al., 2008). At Safe Car, the senior management team had exposure to the well-designed CSR practices of their foreign joint venture partners. In the light of the familiarity with the universal CSR practices of the joint venture partners, the CSR programme was jointly negotiated (without middle/supervisory managers/employee involvement) and subsequently imposed on the affiliates and subsidiaries of Safe Car group. At the core of the CSR programme was a heavy emphasis placed on economic efficiency and labour productivity, owing largely to the know-how transfer by the joint venture partners. Middle managers talked of the ‘not invented here’ syndrome in the sense that the CSR programme were designed without their involvement and subsequently they felt little sense of ownership of the programme. While a set of operational and tactical plans were deployed to fulfil the minimum level of car safety standards, and tended to characterise Safe Car’s CSR approach, the plan was not linked in any coherent manner with the broad notion of CSR. As a result, the hoped for CSR as a mechanism for ‘shared values, integration of business into the community, and development of human capital’ failed to materialise. The *ad hoc* and partial approach to CSR by the foreign joint venture partners implied that they were not fully committed to their standardized global directives on CSR. To a considerable extent the *ad hoc* approach of the joint venture partners to lay stress on operational excellence as a guileless substitution for CSR was attributed to the government’s support for the foreign auto makers. A review of Iran automotive industry policies reveals that government’s inclination to support foreign car manufacturers and joint venture activities is for two main reasons: to counteract the country’s

industrial shortcomings, and to deflect the US-led economic sanctions against the country (see Peimani, 2003; Storey, 1992).

The ramifications of the dominant personal values attached to the notion of CSR coupled with the government's support to the automotive industry for the management of CSR were two-fold: a strong compliance culture with weak ethical conduct, and an inward-looking/inside-in CSR management. Each of these managerial orientations is explained below.

The dominant personal values attached to the notion of CSR inculcated (as one operations manager put it) "a culture of compliance across the group" which in turn reinforced "an organisation-wide commitment to compliance with mandatory governmental regulations". A senior advisor to the management team captured the feelings of many middle and supervisory level managers on this issue: "We are all regulatory experts. We understand and are aware of the negative consequences of noncompliance with, for example, safety standards of our products, labour legislation etc. So we do whatever we are told to do and we exactly comply with the top management's CSR mandate". According to an HR manager, "The existing managerial approach to CSR does not go beyond the labour law which regulates working conditions, minimum wages, hours of work and health and safety". For several marketing managers, the need for the management-led compliance was core to their marketing campaign as it helped lay the base for "maintaining the customer's confidence in the quality of product and service offerings". Close analysis of the marketing strategy of Safe Car industrial group revealed quite clearly certain contrasting features which played down the importance of a socially responsible corporation. For example, a senior marketing manager remarked that "socially responsible activities such as promoting a culture of traffic safety or training programmes for young drivers which are needed to counteract the country's high rate of traffic fatalities are not integral to our marketing campaign simply because we will not be rewarded or recognised for such activities by our senior management team and automotive industry authority". In a similar vein, the main thrust of the Safe Car's management-led compliance culture for several operations managers was highly suggestive of a business or economic perspective toward CSR. As our analysis of the data and publicly available CSR documentary evidence of Safe Car indicated, top management's CSR action plan centred on (in the words of a production manager) "using CSR as a business opportunity for profit-maximisation, quantifying the cost-benefit analysis of CSR-related programmes, and restricting the scope of CSR to those activities which are governed by law and decrease the costs of non-compliance with the manufacturing and environmental regulatory obligations".

The strong compliance culture with weak ethical conduct paved the way for an inward-looking managerial orientation toward CSR. The key to this managerial orientation was seen as a dual move to get the lower level managerial and non-managerial employees on board through a superficial focus on internal CSR (e.g. work health and safety, technical training) while also fulfilling their managerial self-centred priorities (to the exclusion of external CSR –i.e. those they serve or stakeholders). As one HR manager observed, "What we have as internal CSR is not different from our previous HR system. It is an update on HR policies related to work health and safety and employee training. Yes I should say that employees are more engaged now but this does not give them a greater sense of control over their work activities". As our evidence indicates, the key priority that drove the notion of internal CSR was the ability to react to the increase in Iran's booming cars market. A senior sales executive commented, "The revised HR policies which our top management label it as 'internal CSR' are meant to exercise tight managerial control over the workforce, to increase span of management control, and to meet production deadlines. It is not really to do with concerns over employee's wellbeing, care for customers, respect for society or even empathy with environment" (see for a review of managerial leadership in Iran: Analoui et al.,

2009; Javidan & Carl, 2004; Javidan & Dastmalchian, 1998, Javidan & Dastmalchian, 2003; Soltani, 2010; Soltani et al., 2011; Soltani and Wilkinson, 2011).

In a similar vein, several managers pointed to a continued ambiguity surrounding the impact of foreign partners on the adoption and diffusion of CSR practices in Iran's auto industry. Across the different foreign partners of Safe Car industrial group, there was a tendency on the part of the foreign partners to drift in the direction of the local managers and that their approach to CSR differed significantly from their global CSR concerns. A public relations manager made the nature of this approach sufficiently clear: "the fulfilment of the minimum operational necessities for car and auto parts production is the primary concern of our foreign partners. They simply comply with the government regulations and automotive industry mandates". As our evidence indicates, the foreign partners were seeking to put relations with local firms on a new footing – one which was in line with the 'self-centred priorities of the local management'. Hence, the growing number of global vehicle manufacturers in Iran seems to eschew their global CSR programmes in favour of a management style which engender the immediate interest of the management and the maximization of shareholders' wealth (see Chiou & Shu, 2019; Jamali, 2010; Storey, 1992, pp. 169).

CONCLUSION

It was evident from an analysis of Safe Car that 'the corporation management set the tone for and have the discretion to determine the extent to which their firms engage in CSR' (Matten and Moon, 2008, p. 405; Waldman et al., 2004). Whilst, at least in broad terms, there did appear to be evidence of CSR-related practices across the group, the dominant managerial orientation toward CSR neither bring corporate behaviour up to a level where it was congruent with the prevailing Islamic cultural and societal norms (Ahmad, 2002; Ahmad & Sadeq, 2002; Dusuki, 2008) nor it had resemblance to the underlying premises of CSR (Crane et al., 2008; Carroll, 1999; Visser et al., 2007). The overall trend was incontrovertibly towards more personal/managerial use of CSR. Hence, the crucial importance of a culture of compliance in helping to conjure their "unenlightened self-interest" was very evident. These managerial tendencies have typically carried out implications for the way the CSR was adopted, diffused and instituted. The results revealed that the nature and orientation of the management team was intimately linked with the potential to foster a culture of compliance with "the (minimum) regulatory safety standards of auto industry" and that the latter brought the role of supervisory level managers and employees to the fore as the crucial delivery mechanisms to fulfil the managerial myopic selfishness (de Tocqueville, 2000; Griffiths & Lucas, 1996; Steenbergen, 1935).

Contrary to speculative reports about the potential role of foreign affiliates in determining the propensity of local firms to engage in CSR activities (Cheung et al., 2010; Fukukawa & Teramoto, 2009; Jamali, 2007; Khan et al., 2013; Matten & Moon, 2008; Yin & Zhang, 2012), our findings warn of the false seduction of the developmental promise of foreign firms' adoption and implementation of CSR in developing countries. The foreign firms operating in Iran's auto industry had taken the local managers' interest in preserving authority over CSR programmes as the cue to perpetuate silence over the reality of CSR culture across the industry and to adopt a partial approach to CSR (e.g. an emphasis on mandatory safety standards as surrogate for CSR), thereby fulfilling the local management and their own self-interests (see Frynas, 2005; Jamali, 2010). It was found that the on-going US-led sanctions on Iran's energy sector established a need for the government to seek new sources of revenue (i.e. automotive industry) for the government expenditure (Felsenthal et al., 2013). However, such increasingly pressing need for a reliable
